FOREWORD

From May 13 to 14, 2026, Latvia University of Life Sciences and Technologies hosted the 32nd Annual International Scientific Conference 'Research for Rural Development,' bringing together researchers, experts, and practitioners to discuss current scientific developments and practical solutions for the sustainable development of rural areas.

This year, a total of 139 research contributions were presented, including 88 in-person oral presentations, 23 in-person poster presentations, 24 online oral presentations, and 4 online poster presentations. Registered participants represented 14 countries. A total of 158 participants registered to attend the conference in person, while a further 28 participants took part in the online sessions.

We believe that these Proceedings will serve as a valuable reference for researchers worldwide and will stimulate further research in agriculture, forestry, food and veterinary sciences, engineering, information and communication technologies, environmental sciences, economics, social sciences, and education.

We also sincerely thank all section moderators for their dedication and professionalism, which contributed to productive and meaningful discussions throughout the sessions: A. Spage, S. Ancans, V. Tetere, E. Dubrovskis, G. Mazure, U. Skadins, I. Straupe, S. Vasilevska, L. Licite-Kurbe, I. Grinfelde, I. Stokmane, P. Abolins, T. Rubina, J. Kaneps, J. Pilecka-Ulcugaceva, K. Amatnieks, and Z. Vitolina. We extend our sincere thanks to the conference organizing team and all our colleagues whose dedicated efforts made this event a success.

The 'Research for Rural Development' conference continues to serve as an important platform for international collaboration and scientific exchange, supporting innovation and sustainability in rural regions.

We look forward to welcoming you to the Latvia University of Life Sciences and Technologies next year for the 33rd Annual International Scientific Conference 'Research for Rural Development 2027', which will take place from May 12 to 14, 2027.

Natalija Sergejeva

GENETIC ANALYSIS OF LATVIAN DARK HEAD OLD TYPE BREEDING RAMS

***Dace Barzdina, Daina Kairisa**
Latvia University of Life Sciences and Technologies, Latvia
*Corresponding author's email: dace.barzdina@lbtu.lv

Abstract
To ensure genetic diversity of sheep production, local sheep breeds are included in genetic resource conservation programs, which increases their unique characteristics. The Latvian Dark Head old type (LTvt) sheep breed is an excellent example of how important it is to preserve genetic diversity among farm animals. The aim of the study is to evaluate the genetic diversity of LTvt breeding rams. The study included 126 LTvt breeding rams, which were genetically analysed by their year of birth (2002–2021) and paternal (ram) genealogical line, it is seven. Since 2012, the Latvian Sheep Breeders Association (LAAA) has been determining deoxyribonucleic acid (DNA) profiles by microsatellite loci lengths at the Eurofins Genomic laboratory in Germany. Fourteen microsatellite loci were used for DNA profiling. The results show that greater genetic diversity was obtained in indicators such as the number of different alleles (8.86 ± 0.601), the number of effective alleles (4.55 ± 0.476), Shannon's information index (1.66 ± 0.104) and expected heterozygosity (0.74 ± 0.037) in the group of breeding rams born between 2012 and 2016. The inbreeding coefficient values were close to zero, which indicates the absence of inbreeding. The analysed F-statistics values were negative in most loci, which indicates the excess of heterozygous genotypes in the studied population. Genetic differentiation between ram lines selected in the LTvt population was low (0.006–0.074), indicating low genetic diversity. Analysis of molecular variance showed that most of the genetic variation was between alleles within individual (93%).
Keywords: microsatellite loci, allele, genotype, genetic diversity, and variation.

Introduction

The conservation of sheep genetic resources is particularly important. Their variation is characterised by the compatibility of biodiversity conservation with sustainable agriculture, providing food for the population. Sheep genetic resources include genetic diversity that promotes their unique characteristics, such as disease resistance, ability to adapt to changing climatic conditions, and diverse productivity. Continuous cooperation at national, regional, and global levels is essential to ensure the sustainability and resilience of sheep breeds for future generations.

Although awareness of the importance of conserving animal genetic resources increases each year, their decline persists. Genetic diversity provides an opportunity to obtain or improve the disease resistance of farm animals (Jovanovic et al., 2009). Highly resilient local sheep breeds worldwide are capable of surviving extreme climatic conditions. Such breeds are easy to rear and use for small land management systems, as they require less investment in terms of costs and labour, and can lead to significant developments in sheep breeding (Molotsi et al., 2017).

Comparative genetic analysis shows that although the Latvian Dark Head sheep has similar genetic markers to other Northern European sheep breeds, it also has different genetic characteristics. Studies in the Baltic region using microsatellite loci and mitochondrial DNA have revealed both common ancestors and unique genetic diversity within this breed (Larsson et al., 2024).

The selection of the Latvian Dark Head breed is historically based on sheep breeding by ram lines. In 2014, seven breeding ram lines of this breed were identified: Skaris 0008; Edžiņš 0365; Sīgars 0005; Apollons 0302; Sīmanis 0195; Irbis 0125 and Ikars 0121. A systematic survey of the genetic resources of the Latvian Dark Head sheep breed was started in 2004. The animals had to comply with the criteria set out in the Latvian Dark Head sheep breed conservation program. In order to include typical LTvt animals in the genetic resource program in the future, a new breeding program for the Latvian Dark Head old type sheep breed was developed in 2019 (Latvjas Aitu…, 2024). In addition to all animal performance test evaluations, it introduced an evaluation based on wool growth on the head, belly, and legs.

The preservation of the Latvian Dark Head sheep includes two strategic methods. *In situ*: using support and education programs to encourage farmers to breed local animal breeds (including sheep), and *ex situ*: establishing Gene banks and cryopreserving genetic material with the aim of preserving biological material for future use. The aim of Gene bank is to preserve part of the Latvian Dark Head sheep breed as a gene reserve, without introducing other non-related breeds in future generations, and to use it as a 'mother' breed for sheep crossbreeding, as it improves fertility and milk production and is characterized by good maternal traits, a strong constitution, resistance to disease, and suitability for local conditions (Gene Bank, 2021).

Sheep farms often rely on just a few breeding rams, which can lead to a decrease in genetic diversity within ram lines as certain alleles are lost. Breeds originating from a small number of individuals often exhibit low genetic diversity. If a breeding flock initially relies on a single ram, the genetic profile of the offspring is heavily restricted by the father's limited allele pool. The loss of alleles in a population often indicates genetic drift. This is, especially true in small populations where alleles can be randomly lost by chance, particularly when the number of individuals of one sex is limited. Consequently, even neutral or beneficial alleles may fail to be passed on to offspring purely through random sampling. The loss of alleles can also result from deliberate selection goals. For example, if an individual carries alleles associated with undesirable trait like low fertility, those alleles will be passed on to subsequent generations less frequently or

eliminated entirely (David et al., 2018; Karsli et al., 2020; Ocampo et al., 2016; Tapio et al., 2010).

Materials and Methods

Microsatellite loci, or more exactly, genotype distribution, are used in population genetic calculations to determine the level of relationship between breeds, groups, and individuals (Wagner et al., 2006).

Supported by funding from the Latvian Ministry of Agriculture, the LAAA has conducted DNA profiling since 2012 using microsatellite markers based on allele fragment length analysis at Eurofins Genomics (Germany). DNA profiling allows the origin of an animal to be accurately determined and verified. During this process, the laboratory uses 14 microsatellite loci for DNA profiling, see Table 1. All of the listed microsatellite markers are widely used in sheep genetic research in analyses of allele diversity, population structure, and Hardy-Weinberg equilibrium (HWE) (Al-Atiyat et al., 2018; Saberivand et al., 2010).

In laboratory analyses, each sample is (1) subjected to DNA extraction, (2) a multiple polymerase chain reaction is performed with appropriate primers to synthesize the region of the genome of interest, and (3) the length of the synthesized fragment is determined using a capillary electrophoresis sequencer. The laboratory provided information on the fragment lengths of each sample in all 14 loci. Information on the possible number of nucleotides repeats in the microsatellite loci according to the determined fragment length was found on the website of the University of California Regents' International Sheep Genome Consortium (Archibald et al., 2010). Using the primer sequence, the corresponding location in the sheep genome and the number of repeats at the fragment length in the database were determined. Furthermore, the locations of microsatellites loci on the chromosome were verified. The genetic analysis of the LTvt breeding ram population included in the study was performed according to their year of birth and affiliation to the paternal (ram) genealogical line, see Table 2. In total, data on 126 breeding rams born between 2002 and 2021 were analysed, dividing this period into four-year intervals. In Latvia, Apolons 0302 (46) and Skaris 0008 (27) lines of breeding rams are more commonly used on sheep breeding farms. Less represented rams are from the Edžiņš 0365 and Ikars 0121 lines.

Table 2
Number of breeding rams by year of birth and affiliation to the father (rams) line

Ram line	Ram count by birth year				Total in rams' line
	2002–2006	2007–2011	2012–2016	2017–2021	
Apolons0302	2	9	25	10	46
Edžiņš0365	0	0	0	5	5
Ikars0121	0	1	4	4	9
Irbis0125	0	2	6	5	13
Sīgars0005	1	3	8	1	13
Sīmanis0195	0	2	8	3	13
Skaris0008	1	9	7	10	27
Total by period	4	26	58	38	126

More breeding rams were included in the LTvt breeding program from 2012 to 2016 (58), but breeding rams (5) from the Edžiņš 0365 line were only included in the LTvt breeding program from 2017 to 2021. For the genetic analysis of the population, the following statistical methods were used to calculate allele frequency, heterozygosity, Wright's F–statistic (Wright, 1978), Nei's genetic distance, and the Hardy-Weinberg equilibrium test.

Population genetic diversity was characterized by several indicators that reflect allele diversity and genotype distribution. Population genetics is based on the calculation of HWE equilibrium, which indicates a constant allele and genotype frequency in a population from generation to generation, provided there are no allele mutations, migration, selection, inbreeding, or random genetic drift. The GenAlEx 6.5 software package was used to analyse genetic diversity and population structure in the animals included in the study, dividing them by birth year according to their ram line. Based on genotype and allele frequencies (N), the number of different alleles (Na), the effective number of alleles (Ne), and the observed (Ho) and expected (He) heterozygosity were calculated. Different inbreeding coefficients (F) were calculated and analysed. These help to understand the genetic structure of populations, identify the degree of inbreeding, and determine how genetic variation is distributed at the level of individual relative to its subpopulation (Fis), inbreeding coefficient among populations by year of birth (Fst), and the overall inbreeding coefficient entire population (Fit). Principal Coordinates Analysis (PCoA) was based on and calculated using standard genetic distance (Nei). The number of different alleles (Na) provides a general overview of genotype polymorphism, reflecting how many different alleles exist in a single locus. This is the basis for calculating the effective number of alleles and heterozygosity. The effective number of alleles (Ne) shows the most common alleles based on their frequency. The closer this value is to the Na, the more evenly the alleles were distributed. However, if Ne is much smaller than Na, it means that some alleles dominate, while others are very rare. Shannon's information index (I) compares genetic diversity between populations. Its value indicates the frequency of alleles, if there is one dominant allele in a locus, then I will be lower, but if all of them are common, then I will be higher. To assess the extent to which the number of heterozygous genotypes (Ho, He) in a population has decreased due to random crossing, the inbreeding coefficient (F) is calculated (Peakall & Smouse, 2009).

The aim of the study was to evaluate the genetic diversity of Latvian Dark Head old type breeding rams.

Results and Discussion

By analysing the number of alleles present in 14 loci, it was concluded that a total of 136 alleles were observed in the LTvt breeding ram population. Polymorphic genotypes were observed in 14 loci in all 7 breeding ram lines. In some loci, unique alleles were also observed, which characterize the breeding rams belonging to a certain line, for example, in loci 'OarFCB128' (allele 126), 'OarFCB20' (allele 129), 'MAF65' (allele 117), 'MAF65' (allele 123), 'MMP9' (allele 181) and 'BP28' (allele 215). Analysis of the HWE parameter showed that the LTvt breeding ram population was in equilibrium.

The evaluation of the genetic diversity parameters of breeding rams in the LTvt population by year of birth is shown in Table 3.

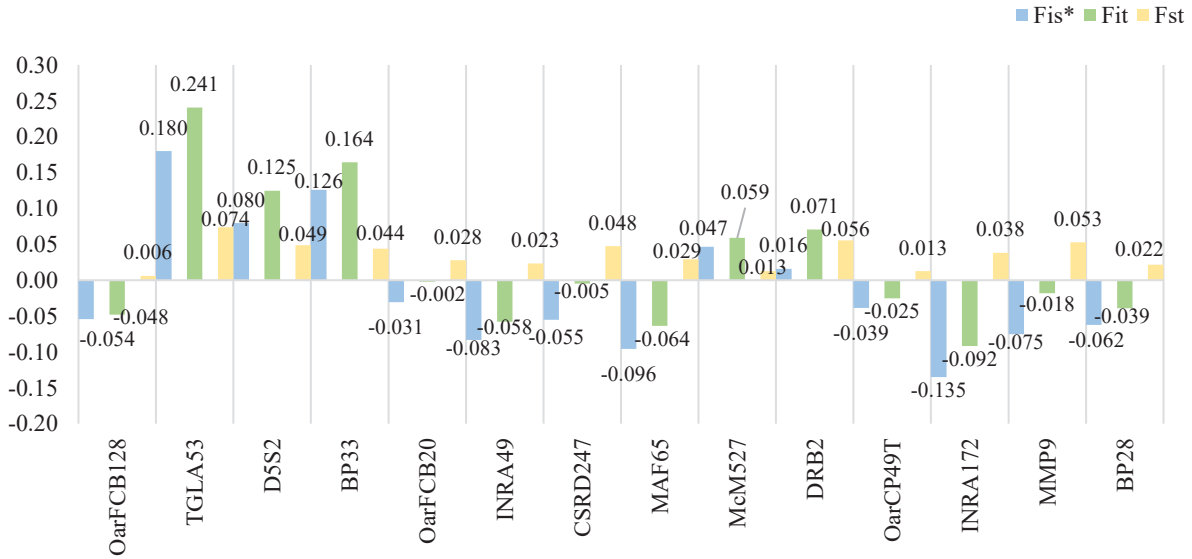
Over the course of the study, a total of 126 breeding rams were analysed, including their 136 alleles and 795 genotypes. Of these genotypes, 657 were heterozygous and 138 were homozygous. This confirms that the LTvt population has good genetic diversity, and it means high heterozygosity and no obvious inbreeding. Genetic diversity indices differ significantly between the birth year groups of breeding rams ($p<0.05$) by Na, I and He.

Table 3

Evaluation of genetic diversity parameters of rams in the LTvt population by birth years

Birth year of the rams	N	Na	Ne	I	Ho	He	F
		$\bar{x} \pm S\bar{x}$					
2000. – 2006.	4	3.79 ± 0.318[a]	2.96 ± 0.273	1.13 ± 0.111[a]	0.70 ± 0.075	0.60 ± 0.054[a]	–0.05 ± 0.035
2007. – 2011.	26	7.50 ± 0.693[b]	4.43 ± 0.451	1.58 ± 0.119[b]	0.70 ± 0.053	0.72 ± 0.048[ab]	0.01 ± 0.046
2012. – 2016.	58	8.86 ± 0.601[b]	4.55 ± 0.476	1.66 ± 0.104[b]	0.71 ± 0.044	0.74 ± 0.037[b]	0.03 ± 0.033
2017. – 2021.	38	7.57 ± 0.677[b]	4.33 ± 0.474	1.59 ± 0.104[b]	0.70 ± 0.037	0.72 ± 0.037[ab]	0.02 ± 0.032
Along/ Mean	126	6.93 ± 0.385	4.07 ± 0.225	1.49 ± 0.060	0.70 ± 0.026	0.70 ± 0.023	–0.02 ± 0.024

Na – number of alleles, Ne – number of effective alleles, I – Shannon's information index, Ho – observed heterozygosity, He – expected heterozygosity, F – inbreeding coefficient.



Different superscript letters within a column indicate statistically significant differences ($p<0.05$).

The group of rams born from 2000 to 2006 exhibited the lowest Na (3.79 ± 0.318), Ne (2.96 ± 0.273) and I (1.13 ± 0.111) values. This indicates reduced allelic richness, low effective allele diversity and low overall genetic diversity. However, because this group contained only four animals, and these results should be interpreted with caution. The highest Na (8.86 ± 0.601), Ne (4.55 ± 0.476), I (1.66 ± 0.104) and He (0.74 ± 0.037) values were observed in the group of breeding rams born between 2012 and 2016, indicating genotype polymorphism and higher genetic diversity, where the breeding rams in this group are genetically more diverse. The observed heterozygosity (Ho) was similar in all groups (0.70–0.71) and did not differ significantly ($p>0.05$) between studied groups. In a Lithuanian study, which also studied Latvian Dark Head breed sheep, the expected heterozygosity (He) (0.698 ± 0.173) was lower than the observed heterozygosity (Ho) (0.712 ± 0.143), which can be explained that the breed has been highly selected in flocks (Grigaliūnaite et al., 2003). The low inbreeding coefficient (F) values indicate that there is no significant inbreeding among the breeding ram groups by birth year. Consequently, no significant deficit of heterozygous genotypes was observed, suggesting that the LTvt breeding ram population is in equilibrium. The negative F value (-0.05 ± 0.035; -0.02 ± 0.024) indicates a slight excess of heterozygote genotypes, while a positive F value (0.01 ± 0.046; 0.03 ± 0.033; 0.02 ± 0.032) indicates a slight deficit of heterozygote genotypes.

Genetic differences between populations and the level of inbreeding are described by F-statistics (Fis, Fit, and Fst). They provide insight into the distribution of genetic diversity at different levels and allow us to characterize genetic differences between individuals, lines, and the population as a whole. The Fis, Fit, and Fst values of genetic differences that characterize the genetic structure of the LTvt population of breeding rams in all 14 loci can be seen in Figure 1.

Figure 1

Distribution of Fis, Fst and Fit values by loci in the ram LTvt population

**Fis – level of inbreeding within a population; Fit – total level of inbreeding across all populations; Fst – genetic differentiation between populations.*

In the LTvt breeding population, heterozygous genotypes exceeded homozygous genotypes in most loci, which was characterized by negative Fis values (from -0.135 to -0.031), but in three loci, 'TGLA53' (0.180), 'D5S2' (0.080) and 'BP33' (0.126), it is positive, where a deficit of heterozygous genotypes is observed. This is often observed in small populations or when animals with specific genotypes have been selected during the selection process. The total heterozygous genotype deficit (Fit) in the LTvt breeding ram population is slightly lower than expected, depending on the year of birth.

In the LTvt breeding poplulation rams' population, the total inbreeding coefficient (Fit) is slightly lower than the level of inbreeding within a population (Fis). The highest Fit values were observed at loci 'TGLA53' (0.241), 'BP33' (0.164) and 'DRB2' (0.071), indicating a persistent deficit of heterozygous genotypes across birth years. Conversely, 8 of the 14 analysed loci exhibited negative Fit values, indicating an excess across the ram groups of birth year.

The total genetic difference in the LTvt breeding ram population by year of birth is determined by the Fst value. If the Fst value is between 0.00 and 0.05, it is low. If it is between 0.06 and 0.15, it is medium, and if the Fst value is more than 0.16, there is a large difference between the animals in the population (Peakall & Smouse, 2009). In most loci, the Fst value varies from 0.01 to 0.07, for example, the lowest value is in the locus 'OarFCB128' (0.006), but the highest is in the locus 'TGLA53' (0.074). This means that the LTvt breeding ram population is genetically similar depending on the animal's year of birth, but there are slight differences in genetic diversity in some loci.

Research conducted by various international authors on local sheep breeds indicates that these populations typically exhibit significant allele diversity. A high number of heterozygous genotypes is often observed, indicating that there is no significant decrease in genetic diversity within breeds. The Fis values of the breeds studied by the authors ranged from 0.110 to 0.752, and negative values were also observed. When describing Fst values, the authors note that in most cases they are low (0.028–0.319), and there is a certain genetic difference between these breeds. In these mentioned studies, the total inbreeding level in relation to the entire population (Fit) ranged from 0.246 to 0.751, and therefore signs of inbreeding or frequent selection were observed in individual loci (Arora et al., 2011; Baumung et al., 2006; Ghazy et al., 2013; Hoda et al., 2009; Hoda & Ajmone, 2012; Kusza et al., 2010; Mukesh et al., 2006; Yilmaz et al., 2014). To evaluate the distribution of genetic diversity at different levels, molecular variance analysis (AMOVA) was performed (Peakall & Smouse, 2009). This helps to understand the extent to which genetic differences exist within the population and between individuals in the population. Molecular variance analysis for the whole LTvt breeding ram population by year of birth can be seen in Table 4.

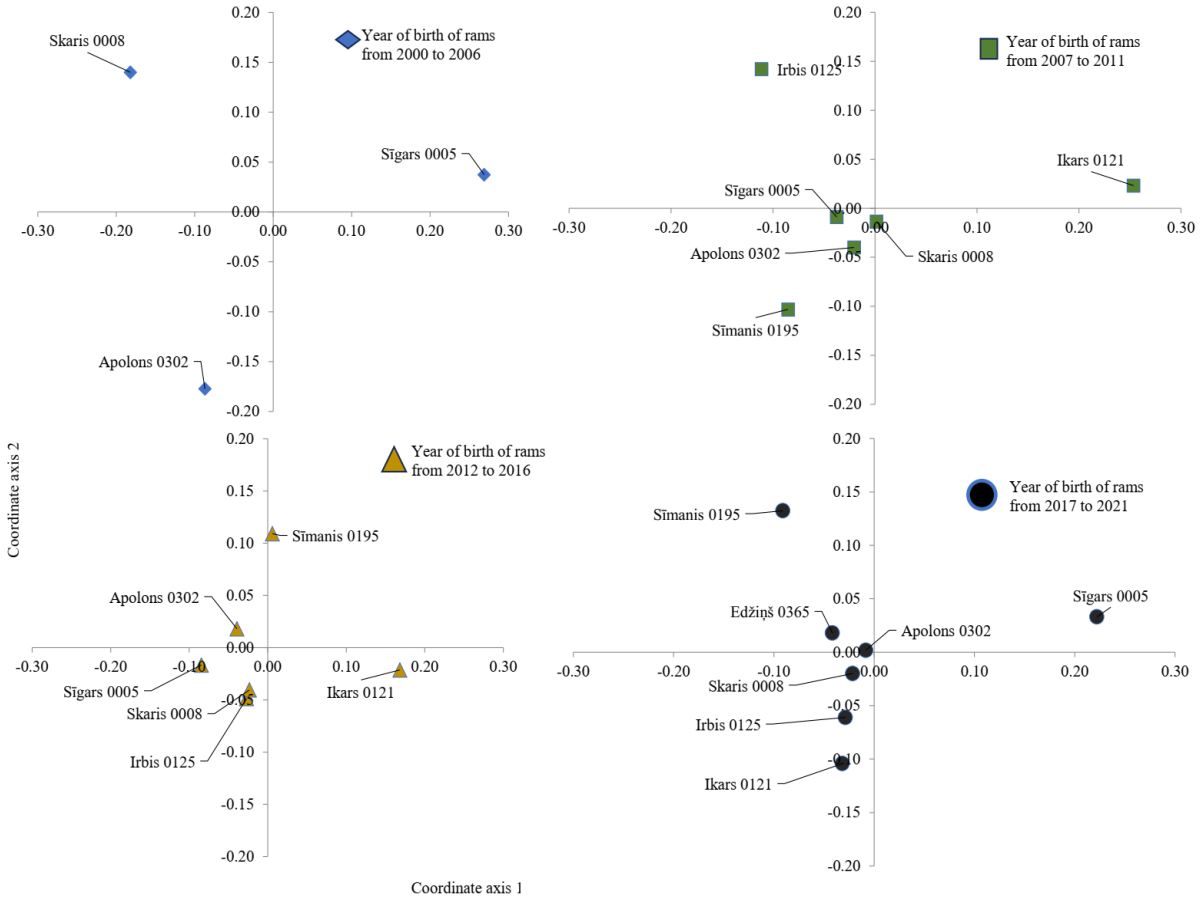
Table 4

Analysis of molecular variance in ram LTvt population by birth year

Source	df	SS	MS	σ^2	%SS
Among line	3	22.86	7.62	0.04	1
Among individual	122	668.97	5.48	0.31	6
Within individual	126	613.00	4.87	4.87	93
Total	251	1304.83	…	5.21	100

df – degrees of freedom, SS – sum of squares, MS – mean square, σ^2 – estimated variance, %SS – Percentage distribution of variation.

When analysing genetic variation among all breeding ram lines depending on their year of birth, these ram lines are genetically similar across years and show slight variation, as indicated by the percentage distribution of variation (%SS) value (1%). Genetic variation between certain breeding ram lines among individual is 6%, where different individuals in the same population are genetically different, but this variation is not wide. When analysing the genetic variation between alleles within individual, this value is higher – 93%, which can be explained by the heterozygosity of the individual, where different alleles are found in the same locus. In a study carried out in Italy with a single sheep breed kept in different regions, these values were similar to the data from our study, as the highest genetic variation between individual alleles was 94.21% (Ceccobelli et al., 2016).



Principal coordinate analysis (PCoA) shows how animals are grouped according to similar or different alleles within a population. The position of breeding rams from a specific line within each LTvt population on the respective axis is indicated by positive or negative numbers. These determine which side of the axis (positive or negative direction) the animals from a specific line are located on. Animals with similar values are closer to each other, while those with opposite values are more different. PCoA analysis was performed for breeding rams of each line depending on their year of birth (Figure 2).

Analysis of the principal coordinates shows that the year of birth of breeding rams is not the main factor in genetic differences, but that the highest allele diversity is at the individual level. Several animals from breeding lines are located on one side of the coordinate axis, for example, animals from the Apolons 0302, Skaris 0008, and Irbis 0125 lines. The animals in these breeding ram lines are genetically similar. However, there are animals in breeding ram lines such as Ikars

0121, Sīmanis 0195, and Sīgars 0005 that are more separated from the main coordinate axis. This indicates a longer genetic distance, which is based on changes in allele frequencies in a certain individual in the year of birth of a certain breeding ram, where these alleles can disappear and reappear when mating with an ewe that may or may not have these alleles. In a study carried out in the Baltic States with local sheep breeds, the genetic characteristics of the Latvian Dark Head sheep breed were similar to the average characteristics of all breeds studied. Animals of the Latvian Dark Head breed formed the most homogeneous group, as the individuals in the group were genetically similar to each other, which can be explained by the extensive selection work carried out during the development of the breed (Tapio et al., 2005).

Figure 2

Genetic relationships among ram birth year and line in LTvt population revealed by PCoA

Conclusions

1. Breeding rams born between 2000 and 2006 had lower genetic diversity, whereas breeding rams born between 2012 and 2016 had higher genetic diversity.
2. Genetic diversity and inbreeding levels in the LTvt breeding ram population showed that most loci had an excess of heterozygous genotypes rather than a deficit, and that there was low to medium genetic variation between breeding ram lines.
3. Molecular variance analysis confirmed that LTvt breeding ram lines are very similar to each other, with the highest genetic variability occurring among the animals themselves.
4. Principal coordinate analysis reflected a similar genetic structure among LTvt ram lines, with slight changes in genetic distance observed across ram birth year periods.
5. The observed heterozygosity in all breeding ram groups by year of birth was similar, the inbreeding coefficient was close to zero, and no significant inbreeding between LTvt breeding ram lines was confirmed.

BLACK SOLDIER FLY LARVAL MEAL AS A PROTEIN SOURCE IN PIG NUTRITION: A REVIEW

***Patrīcija Paula Pauliņa, Lilija Degola**
Latvia University of Life Sciences and Technologies, Latvia
*Corresponding author's email: patricija.paulina@lbtu.lv

Abstract
This review is based on the analysis of recent scientific literature on black soldier fly larvae (BSFL) production, processing and application in pig nutrition. The increasing demand for sustainable protein sources in animal nutrition has stimulated growing interest in insects, particularly black soldier fly (*Hermetia illucens*) larvae, as an alternative feed ingredient. The literature shows that these larvae efficiently convert various organic substrates into high quality biomass, making their production compatible with circular economy principles and supporting sustainable feed systems. BSFL are commonly harvested at the late larval or prepupal stage and processed through thermal treatment, drying and grinding to obtain larvae meal. Depending on processing techniques, both full-fat and defatted meals can be produced. Defatting significantly increases the relative protein content while reducing lipid levels, improving nutritional consistency and storage stability. Chemical analyses show that larvae meal contains high levels of crude protein, often exceeding 45–55% of dry matter, together with valuable lipids. The lipid fraction is characterized by medium-chain fatty acids, particularly lauric acid, which is associated with antimicrobial properties. Processing methods strongly influence the nutritional quality of larvae meals. Drying techniques and blanching conditions affect nutrient availability, protein structure and digestibility. In vitro studies demonstrate that appropriate processing strategies can enhance nutrient utilization of BSFL meals in monogastric animals such as pigs. BSFL meal represents a promising alternative protein source in swine nutrition, offering high nutritional value and the potential to partially replace conventional protein ingredients.
Keywords: black soldier fly larvae, insect protein, pig nutrition, sustainable feed.

Introduction

As the global population continues to grow, the need for animal products is also rising, creating challenges for livestock systems to improve both efficiency and sustainability. Pig production represents an important component of global meat production, and pork accounts for a large proportion of total meat consumption worldwide. However, feed costs represent the largest share of pig production expenses, often accounting for 60–70% of total production costs (Chia et al., 2021). Pig diets frequently contain soybean and fish meal, as these ingredients are good sources of nutrients and protein, but their increasing price and environmental impact have stimulated the search for alternative protein sources (Chia et al., 2021).

Conventional protein sources used in livestock feeding are associated with several sustainability challenges. For example, soybean cultivation is linked to deforestation, high water consumption and greenhouse gas emissions, while fish meal production is strongly influenced by marine resources that are already under pressure due to overfishing. These concerns have led researchers to investigate new feed ingredients that can support efficient animal production while reducing environmental impact (Kar et al., 2021).

Insects are increasingly recognized as a viable alternative to conventional protein sources for animal feed. They are known for their fast development, efficient feed use, and ability to transform organic waste into valuable biomass. Importantly, insect farming requires relatively small land areas and generates lower greenhouse gas emissions compared with conventional livestock production systems (Spranghers et al., 2018). Among the different insect species evaluated for feed applications, the black soldier fly (*Hermetia illucens*) has become more widely studied due to its favourable biological and nutritional characteristics (Spranghers et al., 2018).

Black soldier fly larvae (BSFL) are suitable for livestock diets due to their high content of crude protein, lipids and bioactive compounds. Moreover, the larvae can be produced using organic waste materials, helping to support waste recycling and supporting circular bioeconomy systems (Zhu et al., 2022). Despite the growing interest in insect-based feeds, additional studies are needed to better understand the nutritional properties of BSFL meal and its potential use in pig nutrition (Zhu et al., 2022).

However, despite the growing number of studies on insect feed ingredients, the reported results remain inconsistent, particularly regarding nutrient digestibility and long-term effects in pig production systems.

Therefore, the aim of this review is to summarise and analyse current scientific knowledge regarding BSFL production, processing methods, nutritional composition and their potential use as an alternative protein source in pig feeding systems.

Materials and Methods

This study employed a monographic approach to evaluate existing research on the use of BSFL meal in pig nutrition. The analysis was based on peer reviewed research articles, review papers and experimental studies focusing on insect production, nutrient composition and feeding trials in pigs.

Literature was collected using databases such as Scopus, Web of Science and Google Scholar using keywords 'black soldier fly', 'pig nutrition' and 'insect protein'. Studies were selected based on relevance, publication date and scientific quality. In total, 35 scientific publications were included in the analysis, of which all were experimental studies. The selected studies were

published between 2015 and 2025. The reviewed publications included studies conducted in different countries with advanced research programmes in animal production and feed technology. Particular attention was given to studies investigating the production of BSFL, their chemical composition and how their inclusion in pig diets affects growth performance, nutrient digestibility, gut health and meat quality.

Although a systematic review protocol (e.g., PRISMA) was not applied, efforts were made to include recent and relevant peer reviewed studies to ensure a comprehensive overview of the topic.

The results of these studies were synthesised to assess the current scientific understanding of the role of insect-based protein sources in swine feeding systems.

Results and Discussion

Production and biological characteristics of black soldier fly larvae

The black soldier fly (*Hermetia illucens*) is a saprophagous dipteran species capable of converting a wide range of organic substrates into nutrient-rich biomass suitable for feed production (Nguyen et al., 2015). The species undergoes complete metamorphosis, comprising egg, larval, pupal and adult stages. Depending on environmental conditions, eggs generally hatch within 4 days, larval development lasts approximately 13–16 days, the pupal stage requires around 14 days, and adults survive for approximately 5–8 days (Laursen et al., 2024). Adult flies are distributed across tropical, subtropical and temperate regions, while larval development and survival are strongly influenced by environmental conditions, particularly temperature and substrate composition (Chia et al., 2018).

The larval stage is characterized by rapid growth, with larvae typically reaching the prepupal stage within 15 – 22 days and exhibiting growth rates ranging from 0.0014 to 0.0056 g day^{-1}, depending on substrate (Bava et al., 2019; Nguyen et al., 2015). BSFL also demonstrate efficient utilization of organic materials, achieving waste reduction index (WRI) values of 3.01–4.90 and feed conversion efficiency (ECD) values of 0.25–0.36, while reducing organic waste mass by approximately 50% or more under suitable rearing conditions. BSFL have been successfully reared on diverse substrates, including poultry feed, kitchen waste, pig manure, fruit and vegetable waste, fish-processing residues, brewery by-products and distillers' grains (Bava et al., 2019; Nguyen et al., 2015). In a comparative study evaluating different organic waste streams, kitchen waste increased waste reduction by 67.9% relative to the control poultry feed and yielded the highest larval biomass (679.9 mg per three larvae), compared with approximately 580 mg per three larvae in the control group (Nguyen et al., 2015). Similarly, larvae fed maize distillers reached final weights of up to 1.97 g, while those reared on a control hen diet reached 2.29 g before the prepupal stage (Bava et al., 2019).

The nutritional composition of BSFL varies according to the substrate used during rearing. Crude protein concentrations ranging from 39.9 to 43.1% of dry matter (DM) have been reported in prepupae reared on chicken feed, vegetable waste, biogas digestate and restaurant waste (Spranghers et al., 2016). Likewise, larvae produced on different by-products contained between 37.2 and 52.3% crude protein on a DM basis, indicating considerable flexibility in nutrient composition depending on the feeding substrate (Tschirner & Simon, 2015). Due to their ability to efficiently transform low-value organic materials into protein- and lipid-rich biomass, BSFL have gained increasing attention as a sustainable ingredient for animal feeding systems (Oonincx et al., 2015).

BSFL can be reared on a wide range of organic substrates, including agricultural residues, food processing by products and livestock manure (Hao et al., 2023).

Beyond its nutritional value, BSFL production contributes to improved nutrient recycling and resource efficiency (Parodi et al., 2021). During manure bioconversion, BSFL were shown to recover and retain approximately 12.5% of the supplied dry matter, 13% of carbon, 25% of nitrogen, 14% of gross energy, 8.5% of phosphorus and 9% of potassium in larval biomass within a nine-day period, demonstrating their capacity to redirect nutrients from waste streams into valuable biological products (Parodi et al., 2021). This highlights the dual role of BSFL as both a feed ingredient and a biological tool for waste valorisation.

BSFL are widely recognized for their capacity to efficiently reduce organic waste. The effectiveness of this process depends on substrate composition. Larvae reared on tofu by-products achieved greater larval biomass, higher bioconversion rates and higher protein and lipid yields than larvae reared on food waste or vegetable substrates, indicating substantial differences in nutrient conversion efficiency among feedstocks (Hosseindoust et al., 2023). Similarly, prepupae reared on different organic substrates contained between 399 to 431 g kg^{-1} DM crude protein and lipid between 218 to 386 g kg^{-1} DM lipids, demonstrating the strong influence of substrate quality on biomass composition (Spranghers et al., 2016).

The growth and development of BSFL are strongly influenced by environmental conditions, particularly temperature. Larvae successfully completed development between 15 and 35 °C, whereas survival and growth performance declined substantially at lower temperatures (Shumo et al., 2019). Population growth was greatest at approximately 30 °C, where the intrinsic rate of increase reached 0.127 and population doubling time was reduced to 5.5 days, indicating highly suitable conditions for mass production (Chia et al., 2018). In addition, substrate characteristics interact with temperature effects, as larvae reared on brewers' spent grain exhibited greater tolerance to temperature fluctuations and produced more biomass than those reared on cattle manure (Shumo et al., 2019).

The larval stage plays a key biological role in organic matter decomposition and nutrient transformation. Rapid biomass accumulation is supported by extensive microbial activity within the digestive tract (Zhineng et al., 2021). Metagenomic analyses revealed that the BSFL intestine contains more than 11,000 bacterial species involved in polysaccharide metabolism, membrane transport, energy metabolism and nutrient conversion pathways (Zhineng et al., 2021). Furthermore, manure conversion studies identified *Proteobacteria*, *Firmicutes* and *Bacteroidetes* as the dominant bacterial phyla, while approximately 90 and 109 newly established bacterial genera were detected during chicken and swine manure conversion, respectively (Ao et al., 2020). Functional analyses suggested that these microbial communities contribute directly to amino acid metabolism and nutrient utilization efficiency, thereby supporting protein accumulation in larval biomass (Ao et al., 2020).

BSFL reared on tofu by-products produced the highest protein yield (1.45 kg per clutch) and lipid yield (1.23 kg per clutch), compared with 1.25 and 1.20 kg per clutch for food waste and 1.05 and 0.96 kg per clutch for vegetable substrates, respectively. In contrast, vegetable-based substrates resulted in the highest protein conversion rate (21.44%) and lipid conversion rate (25.55%), compared with 8.69% and 16.48% for tofu by-products, and 11.30% and 11.35% for food waste, respectively (Hosseindoust et al., 2023). Likewise, larvae reared on thermally pre-treated sewage sludge contained between 44 and 54% crude protein and between 21 and 25% lipids, while thermal pre-treatment at 90°C for 16 h increased protein and lipid yields by 69% and 71%, respectively, compared with untreated sludge. The larvae were reared for 15 days on the pre-treated substrate and subsequently harvested, inactivated, dried and proceseed into meal for protein and lipid analyses (Liew et al., 2023).

Processing of black soldier fly larvae into meal

After harvesting at the late larval or prepupal stage, typically after approximately 14–18 days of larval development under optimal rearing conditions (25 – 30°C), BSFL are processed into insect-derived feed ingredients suitable for livestock nutrition. Depending on the intended product, harvested larvae may be processed into full-fat BSFL meal, partially or fully defatted BSFL meal, or BSFL oil. Defatted meals are produced by removing part or most of the lipid fraction from dried larvae, thereby increasing the relative crude protein concentration, whereas the extracted lipid fraction can be further processed and used as BSFL oil in animal feeds. The processing methods applied to the larvae play critical role in determining the nutritional quality, safety and storage stability of the final product (Chia et al., 2018; Oh et al., 2024., Zozo et al., 2022).

The most common processing procedure includes several stages, such as washing, thermal treatment, drying and grinding. The processing of BSFL generally includes cleaning, blanching or thermal treatment to inactivate enzymes and microorganisms, grinding, drying (e.g., ove-, microwave- or freeze-drying), and milling (Zozo et al., 2022). Depending on the intended application, and additional defatting step may be applied. In solvent-based defatting, lipids are extracted using organic solvents such as hexane and isopropanol, followed by solvent removal and further grinding of the residual meal. Defatting reduces the fat content and increases the relative protein concentration, resulting in partially or fully defatted BSFL meal with improved storage stability and reduced risk of lipid oxidation (Zozo et al., 2022). Thermal treatment is commonly used to inactivate microorganisms and enzymes that could otherwise reduce product quality during storage. Drying methods may include microwave drying, hot-air drying and freeze drying, depending on the processing technology used (Son et al., 2023). For example, microwave drying has been performed at 80 °C for 32 minutes, whereas hot-air drying has been conducted at 60 °C for 17 hours. In addition, blanching in boiling water or in a 2% citric acid solution for 5 min is often applied before drying to reduce microbial contamination and inactivate enzymes. After drying, the larvae may be defatted by mechanical oil extraction and subsequently ground into a fine powder that can be incorporated into feed formulations (Son et al., 2023).

Processing conditions strongly influence nutrient availability and digestibility. For example, drying methods involving higher thermal exposure, such as infrared drying at 95 °C for 12 min, resulted in lower crude protein digestibility compared with hot-air drying at 65 °C for 24 h, microwave drying, or freeze drying (Oh et al., 2024; Son et al., 2023). Similarly, blanching prior to drying reduced nitrogen and amino acid digestibility compared with hot-air drying alone. Therefore, selecting appropriate processing techniques is essential to maintain the nutritional value of insect feed ingredients (Oh et al., 2024; Son et al., 2023).

Son et al. (2023) reported that hot air drying at 60 °C for 17 h improved nitrogen digestibility compared with microwave drying at 80 °C for 32 min, increasing the *in vitro* ileal disappearance of nitrogen from 84.4% to 86.7% ($p<0.05$). These findings demonstrate that thermal processing conditions can influence nutrient availability for pigs.

However, the reported results are not entirely consistent, which may be explained by differences in experimental conditions, including variation in BSFL inclusion levels, processing methods, animal age and duration of feeding trials. Notably, the nutritional composition of BSFL meal is influenced by rearing substrate, which may further contribute to variability in reported outcomes.

Chemical composition and nutritional value of black soldier fly larvae meal

The chemical composition of BSFL meal has been extensively investigated due to its potential as an alternative protein source in animal nutrition. The nutritional value of BSFL is largely determined by its

protein, lipid, amino acid and mineral composition, all of which can be influenced by rearing substrate and processing methods.

BSFL meal is characterized by a crude protein content ranging from approximately 40 to 56% on a dry matter basis, depending on larval age and rearing substrate, which is comparable to soybean meal (44–48% crude protein) and lower than fish meal (60–72% crude protein). In addition, BSFL contains substantial amounts of lipids and various bioactive compounds (Eke et al., 2025). In larvae reared on different food waste mixture, crude protein concentrations reached 44.5% DM, while lipid content remained close to 30% DM, confirming the ability of BSFL to convert organic residues into nutrient-rich biomass suitable for feed applications (Eke et al., 2025). Similarly, BSFL reared on agro-industrial by-products showed significant variation in chemical composition, with crude protein concentrations ranging from 22.9% to 39.6% DM depending on the rearing substrate (Meneguz et al., 2018).

The nutritional composition of BSFL meal is strongly affected by processing. Zozo et al. (2022) reported that full-fat BSFL flour contained 45.8% crude protein and 25.8% fat, whereas defatted BSFL flour contained 56.1% crude protein and only 4.8% fat. Defatting therefore increased protein concentration by approximately 10 percentage points while substantially reducing lipid content, improving the suitability of BSFL meal as a concentrated protein ingredient for monogastric diets (Zozo et al., 2022).

In addition to crude protein content, the nutritional value of BSFL meal depends on protein digestibility and amino acids availability. Chen et al. (2019) demonstrated that BSFL protein exhibited a slower nitrogen solubilisation rate during the initial stages of digestion than whey protein, although the release of low-molecular-weight peptides during pancreatic digestion was comparable. These findings suggest that BSFL protein may provide a more gradual supply of amino acids within the gastrointestinal tract (Chen et al., 2019).

BSFL lipids are characterized by a high proportion of medium-chain fatty acids, particularly lauric acid (C12:0), which may account for up to 60% of the total fatty acid profile. Spranghers et al. (2018) reported that extracted BSFL fat exhibited antimicrobial activity against *D-streptococci* under *in vitro* conditions, with approximately 2.2 log reductions observed at the highest inclusion level of 1.50 g fat 100 mL^{-1} medium (equivalent to 0.87 g C12:0 100 mL^{-1}). In feeding trials with weaned piglets, diets containing full-fat and defatted BSFL resulted in approximately 0.5 log reductions in *D-streptococci* counts in the stomach and proximal small intestine compared with the control diet, without negatively affecting average daily gain, feed intake or feed conversion ratio (Spranghers et al., 2018).

Another important aspect of BSFL meal is its amino acid profile. Essential amino acids such as leucine, lysine, valine and histidine were identified as the predominant amino acids in BSFL meal processed using different drying methods, supporting its suitability as a protein source for livestock diets (Zulkifli et al., 2022). The amino acid composition of BSFL meal is generally comparable with conventional protein ingredients, although differences in amino acid digestibility may require adjustments during feed formulation (Zulkifli et al., 2022).

Although BSFL meal contains all essential amino acids required for pig growth, some studies have reported slightly lower digestibility values compared with fish meal. Hosseindoust et al. (2023) observed higher apparent ileal digestibility of arginine, histidine, leucine, threonine, isoleucine and phenylalanine in fish meal diets than in BSFL meal diets. However, average amino acid digestibility did not differ significantly among treatments, indicating that BSFL meal can provide comparable overall amino acid availability for pigs. Furthermore, thermal processing and extrusion of BSFL meal tended to improve amino acid digestibility (Hosseindoust et al., 2023).

Table 1 presents the nutritional composition, selected amino acids and fatty acid profiles of BSFL-derived products with conventional feed ingredients used in pig diets. The data indicate that crude protein concentrations in full-fat BSFL meal (45–50%) are comparable to soybean meal (44–48%), while defatted BSFL meal may contain up to 56% crude protein, approaching values reported for fish meal (55–60%) (Zozo et al., 2022). In addition, BSFL meal provides considerable amounts of essential amino acids, particularly leucine, lysine, valine and histidine, supporting its suitability as a protein source for pig nutrition (Zulkifli et al., 2022). Compared with conventional protein sources, BSFL-derived products are characterized by a distinctive fatty acid profile rich in lauric acid, which accounts for approximately 36–42% of total fatty acids in BSFL oil and full-fat meal (van Heugten et al., 2022; Spranghers et al., 2018). This fatty acid composition may provide additional functional benefits related to gut health, antimicrobial activity and microbial regulation in pigs (Spranghers et al., 2018).

These nutritional characteristics have contributed to increasing in BSFL meal as a feed ingredient for pigs. The high productivity and adaptability of BSFL make them particularly suitable for large-scale insect farming. Research findings in pigs suggest that replacing conventional protein sources with BSFL meal does not negatively affect growth performance or feed efficiency (Chia et al., 2019; Crosbie et al., 2021). More recently, defatted BSFL meal containing 6.26% ether extract (fat), compared with 9.00% in fish meal and 11.44% in hydrolyzed BSFL meal, improved average daily gain, feed conversion ratio and feed cost per kilogram of gain compared with conventional fish meal diets in weaned pigs, further supporting its potential as a sustainable protein source for animal nutrition (Lee at al., 2024).

Table 1

Nutritional composition of black soldier fly larvae meal compared with conventional protein sources used in pig diets

Feed ingredient	Crude protein (%)	Fat (%)	Key amino acids (% DM)	Main fatty acids (% total FA)	Notable characteristics	Reference
Soybean meal	44–48	1–2	Lys 2.8–3.0; Leu 3.4–3.8	Linoleic acid 50–55; Oleic acid 20–25	widely used plant protein source in pig diets	Nørgaard et al., 2021
Fish meal	55–60	8–10	Lys 4.5–5.5; Met 1.5–2.0	EPA + DHA 15–30	high digestibility	Chia et al., 2021
BSFL meal (full-fat)	45–50	25–35	Leu 2.7–3.0; Lys 2.3–2.8; Val 2.0–2.4; His 1.0–1.4	Lauric acid 36–42; Palmitic acid 14–15; Oleic acid 13–14; Linoleic acid 17–18	antimicrobial properties, high energy	Spranghers et al., 2018; Zozo et al., 2022
BSFL meal (partially defatted)	50–56	10–15	Leu 2.7–3.1; Lys 2.4–2.9	Lauric acid 30–40; Linoleic acid 15–18	Better protein concentration and feed formulation flexibility	Lee et al., 2024
BSFL meal (defatted)	50–56	4–8	Leu 2.8–3.2; Lys 2.5–3.0	Residual lauric acid 15–25	suitable as concentrated protein ingredient	Zozo et al., 2022
BSFL oil	-	>95	-	Lauric acid ~37; Linoleic acid ~17; Palmitic acid ~14; Oleic acid ~13; Myristic acid ~10	antimicrobial activity, alternative lipid source	van Heugten et al., 2022
Soybean oil	-	99–100	-	Linoleic acid 50–55; Oleic acid 20–25; Palmitic acid 10–12	rich in unsaturated fatty acids	Buffoni et al., 2025; van Heugten et al., 2022

Notes: Lys – lysine, Leu – leucine, Met – methionine, Val – valine, His – histidine; EPA – eicosapentaenoic acid, DHA – docosahexaenoic acid.

Effects of black soldier fly larvae meal in pig diets

Several experimental studies have evaluated the effects of including BSFL meal in pig diets, and the majority of findings indicate that insect-derived ingredients can partially or completely replace conventional protein sources without compromising animal performance. The magnitude of the response, however, depends on inclusion level, processing method and the production stage of the animals.

Supplementation with BSFL oil resulted in a linear increase in growth performance. Nursery pigs receiving 6% BSFL oil achieved a final body weight of 30.0 kg compared with 28.4 kg in pigs fed corn oil, while average daily gain increased by approximately 7% and feed efficiency improved significantly during the first two feeding phases (van Heugten et al., 2022). In post-weaning pigs, replacing soybean oil with a BSFL oil blend for 39 days did not significantly affect growth performance. Final body weight was 27.58 kg in pigs receiving BSFL oil compared with 27.03 kg in pigs fed soybean oil, while overall average daily gain was 0.534 and 0.513 kg d^{-1}, respectively. Average daily feed intake remained similar between treatments (0.692 vs 0.672 kg d^{-1}), as did gain-to-feed ratio (0.763 vs 0.765 kg d^{-1}), indicating that BSFL oil can effectively replace conventional vegetable oil without impairing pig performance (Buffoni et al., 2025). These findings suggest that BSFL oil can be incorporated into pig diets without detrimental effects on growth performance or gut microbial development. In a 61-day feeding trial with weaned piglets, Biasato et al. (2019) evaluated the inclusion of partially defatted BSFL meal at 5% and 10% of the diet. In weaned piglets, inclusion of 5% and 10% partially defatted BSFL meal increased final body weight from 31.88 kg in the control group to 32.23 and 33.06 kg, respectively. Total weight gain increased from 25.78 kg in the control group to 26.14 kg and 26.96 kg in the BSF5 (5% inclusion) and BSF10 (10% inclusion) groups, while average daily gain increased from 0.42 to 0.43 and 0.44 kg d^{-1}, respectively; however, these differences were not statistically significant ($p>0.05$). Feed conversion ratio remained similar among treatments (1.71, 1.70 and 1.70, respectively). Apparent digestibility of crude protein ranged from 76.6 to 79.5%, and villus height-to-crypt depth ratio varied between 3.35 and 3.72, indicating that dietary BSFL meal did not adversely affect nutrient utilization or gut morphology (Biasato et al., 2019). Similarly, Crosbie et al. (2021) reported that replacing 25% or 50% of conventional animal protein sources with full-fat BSFL meal resulted in similar average daily gain (496 g d^{-1}), feed intake (743 g d^{-1}) and final body weight (27.6 kg) compared with antibiotic-containing

nursery diets, while gut morphology and immune response remained unaffected.

The effects of BSFL meal on gut health and metabolism have also been investigated. Feeding pigs, a diet in which BSFL served as the sole protein source altered intestinal microbial composition and resulted in the appearance of plasma metabolites such as sarcosine, methionine sulfoxide, α-aminobutyric acid and taurine, suggesting metabolic adaptations associated with improved intestinal functionality and host health (Kar et al., 2021). In addition, dietary BSFL reduced the relative abundance of *Mycoplasma* in the ileal digesta of nursery pigs compared with conventional protein diets, indicating a potential beneficial effect on intestinal microbial balance (Song et al., 2024).

Another important aspect of pig production is meat quality. Zhu et al. (2022) reported that replacing part of the fish meal and soybean meal with 4% or 8% full-fat BSFL meal significantly increased intramuscular fat content compared with the control diet. Growing pigs receiving 8% BSFL meal achieved the highest average daily gain (0.56 kg d^{-1}) compared with pigs fed the control diet (0.47 kg d^{-1}) or 4% BSFL meal (0.46 kg d^{-1}; p=0.029). In addition, first intercostal backfat thickness increased from 16.13 mm in the control group to 24.04 mm in pigs fed 8% BSFL meal, p=0.024. Intramuscular fat content also increased significantly from 1.49% in control pigs to 1.65–1.74% in pigs receiving BSFL meal (p=0.013), while drip loss decreased from 0.17% to 0.12–0.13% (p=0.026), indicating improvements in several meat quality traits (Zhu et al., 2022). Metabolomic analyses further revealed increased concentrations of several free amino acids and lipid-related metabolites in muscle tissue, suggesting positive modifications of meat quality characteristics (Zhu et al., 2022).

Positive responses have also been reported when fish meal was replaced with BSFL meal (Chia et al., 2021). In finishing pigs, replacing fish meal with BSFL meal increased carcass weight from 75.8 kg in the control group to 90.6, 88.3 and 94.4 kg in pigs receiving 50%, 75% and 100% fish meal replacement, respectively (p<0.001). Fasted body weight increased from 98.0 kg in the control group to 115.6–120.9 kg in BSFL-fed pigs, while dressing percentage remained similar among treatments (77.3–79.1%). These results indicate that BSFL meal can successfully replace fish meal without compromising carcass quality (Chia et al., 2021). Likewise, in growing pigs, replacing fish meal with BSFL meal at levels from 25% to 100% did not significantly affect final body weight, which ranged from 50.4 to 55.1 kg compared with 55.0 kg in the control group (p=0.474). Average daily gain ranged between 0.53 and 0.62 kg d^{-1} across all treatments, while average daily feed intake and feed conversion ratio remained comparable among groups. Return on investment varied from 132.4 to 162.4%, with no significant differences among dietary treatments (p=0.318), demonstrating that BSFL meal can replace fish meal without negatively affecting production or economic performance (Chia et al., 2019).

More recent studies have further confirmed the nutritional value of BSFL meal (Lee et al., 2024). In weaned pigs, complete replacement of fish meal defatted BSFL meal increased final body weight at week 6 from 21.80 kg in the fish meal group to 23.68 kg (p=0.017). Overall average daily gain increased from 324.1 to 369.4 g d^{-1} (p=0.001), while feed conversion ratio improved from 2.06 to 1.85 kg feed kg^{-1} gain (p=0.031). Feed cost per kilogram of gain decreased from USD 1.38 to USD 1.21 (p=0.009), indicating improved biological and economic efficiency of the defatted BSFL meal diet (Lee et al., 2024). Similarly, Noh et al. (2025) demonstrated that inclusion of BSFL larvae at levels replacing 25%, 50% or 100% of fish meal did not significantly affect body weight, average daily gain, feed intake or gain-to-feed ratio during the four-week nursery period (p>0.05). Final body weight ranged from 16.05 to 16.91 kg compared with 16.76 kg in the control group, while overall average daily gain ranged from 306 to 337 g d^{-1} compared with 332 g d^{-1} in the control treatment. Feed efficiency remained similar among groups, with gain-to-feed ratios ranging from 0.63 to 0.73. Differences in feed efficiency outcomes among studies may be related to variations in the type of BSFL product used (defatted versus partially defatted meal), inclusion level, replacement strategy (fish meal versus soybean meal), experimental duration, and animal age. Furthermore, feed efficiency was expressed as gain-to-feed ratio (G) by Noh et al. (2025), whereas Biasato et al. (2019) reported feed conversion ratio (FCR), making direct comparisons between studies more difficult. These findings indicate that BSFL meal can replace fish meal in weaning pig diets without compromising growth performance (Noh et al., 2025).

A summary of selected studies evaluating the inclusion of BSFL meal in pig diets is presented in Table 2. Collectively, the reviewed studies demonstrate that BSFL meal can replace between 25% and 100% of conventional protein ingredients depending on the production stage and dietary formulation. Across most experiments, average daily gain, feed intake, feed conversion ratio, nutrient digestibility, blood parameters and gut morphology remained comparable to conventional diets, while several studies reported additional benefits such as improved carcass traits, increased intramuscular fat content, favourable microbiota modulation and improved feed efficiency (Biasato et al., 2019; Chia et al., 2019, 2021; Lee et al., 2024; Zhu et al., 2022). Despite these promising results, several factors must still be considered before large scale adoption of insect meal in pig diets. These include production costs, regulatory frameworks and consumer acceptance. Although insect farming has significant environmental advantages, the current cost of insect meal is still relatively high compared with conventional feed ingredients. Continued technological development and scaling up of production systems may help reduce costs in the future.

Table 2
Summary of studies evaluating the inclusion of black soldier fly larvae meal in pig diets

Reference	Animal stage		Main findings
Biasato et al., 2019	weaned piglets	Partially defatted 5–10%	no negative effects on growth performance, nutrient digestibility or blood parameters
Zhu et al., 2022	growing pigs	Full-fat 4–8%	improved growth performance and increased intramuscular fat content
Chia et al., 2021	finishing pigs	Non-defatted 25–100% replacement of fish meal	higher carcass weight and acceptable meat quality
Spranghers et al., 2018	weaned piglets	Full-fat 4–8% and defatted 5.4%	antimicrobial effects in the gut due to lauric acid; no negative impact on performance

Overall, BSFL meal can partially replace conventional protein sources in pig diets without negatively affecting growth performance, although responses may vary depending on processing methods, inclusion levels and experimental conditions.

Despite the growing number of studies investigating BSFL meal in pig nutrition, several limitations and inconsistencies can be identified across the available literature. A key issue is the substantial variation in experimental design, including differences in animal age, BSFL inclusion levels, processing techniques, and trial duration. This heterogeneity complicates direct comparison between studies and likely contributes to the inconsistent results reported in the literature. Moreover, the nutritional composition of BSFL meal is not uniform, as it is strongly influenced by the rearing substrate and processing conditions. Fluctuations in protein and lipid content, as well as in the amino acid profile, can affect digestibility and animal performance. Consequently, studies using BSFL meal from different sources or processing methods may produce divergent outcomes. Another limitation is the predominance of short-term trials, particularly those conducted with weaned piglets. While these studies generally indicate no negative effects on growth performance in the short term, there is a lack of data on long-term impacts, including animal health, reproductive performance, and carcass quality. Moreover, although some studies suggest positive effects on gut microbiota and metabolic activity, the mechanisms underlying these effects remain insufficiently understood. In particular, the role of bioactive compounds such as lauric acid, warrants further investigation, especially under practical farming conditions.

Future research should focus on standardising BSFL production and processing methods, conducting long-term feeding trials and evaluating economic feasibility under practical farming conditions.

Conclusions

1. Black soldier fly larvae (*Hermetia illucens*) represent a promising alternative protein source for pig nutrition due to their high crude protein content, favourable amino acid profile and presence of biologically active compounds such as lauric acid.
2. The production of BSFL is compatible with circular economy principles because the larvae can efficiently convert organic waste streams and agricultural by-products into valuable biomass suitable for animal feed.
3. The nutritional composition of BSFL meal may vary depending on the rearing substrate, processing methods and level of defatting, but generally the meal contains 40–60% crude protein and a lipid fraction rich in medium-chain fatty acids.
4. Experimental feeding trials have demonstrated that partial inclusion of BSFL meal in pig diets can maintain normal growth performance, nutrient digestibility and animal health, confirming its potential as a substitute for conventional protein sources such as soybean meal or fish meal.
5. Despite the promising potential of BSFL meal, further research is required to standardize production methods and evaluate long-term effects under practical farming conditions. Economic feasibility and consumer acceptance also remain important factors influencing the wider adoption of insect-based feed ingredients.

Abstract
This study evaluated the effects of origin, farm, and observation period on laying intensity and average egg mass in free-range Australorp hens. A total of 1,032 daily records were analysed, with observations grouped into three production periods (Day 1–25, Day 26–45, and Day 46–129). The results demonstrated that laying intensity was significantly affected by origin ($p < 0.05$) and farm ($p < 0.05$), with the highest values observed during the peak production phase (Day 26–45). Hens of rooster David origin consistently showed higher laying intensity compared to Adisor across all periods. In contrast, average egg mass was significantly influenced by origin ($p < 0.05$) and period ($p < 0.05$), but not by farm, with Adisor hens producing slightly heavier eggs. Egg mass increased progressively with time, reaching the highest values in the late production period (Day 46–129). Regression analysis revealed a significant positive relationship between average egg mass and laying intensity ($p < 0.05$), indicating that higher egg mass was associated with increased productivity. Overall, the observation period was the dominant factor affecting both traits, while origin contributed consistently to performance differences. These findings highlight the importance of genetic background and production stage in optimizing laying performance in free-range poultry systems.
Keywords: laying intensity, egg mass, origin, production period, Australorp hens.

Introduction

Poultry production plays a crucial role in ensuring food security and providing high-quality animal protein worldwide. In many developing regions, poultry production contributes significantly to nutrition, economic development, and rural livelihoods (Shahid et al., 2025). Egg production traits, including egg number, egg weight, and egg quality, are key indicators of productivity and are influenced by both genetic and environmental factors (Shahid et al., 2025).

Genetic background is one of the most important determinants of performance in laying hens. Intensive selection in commercial layer breeding has focused on increasing egg production, egg mass, and feed efficiency, resulting in substantial improvements over time (Thiruvenkadan et al., 2010). However, such selection has also reduced genetic variability in certain traits and emphasized the need to consider multiple characteristics simultaneously, including egg quality and adaptability (Thiruvenkadan et al., 2010). In addition, genetic factors influence not only production traits but also welfare-related characteristics such as behaviour, bone strength, and resistance to environmental factors (Fernyhough et al., 2020).

The Black Australorp breed is widely recognized for its high egg production potential and adaptability. It has been reported that Australorp chickens demonstrate strong productive and reproductive performance, including high egg production rates and favourable egg quality traits (Shahid et al., 2025). Moreover, studies have shown significant relationships between production traits, such as body weight, egg weight, and reproductive performance, indicating that these traits are biologically interconnected (Shahid et al., 2025).

Environmental factors, particularly housing systems and management conditions, also play a critical role in determining productivity. Alternative production systems, including free-range housing, allow birds to express natural behaviours but may introduce additional variability in performance outcomes (Usman et al., 2020). The interaction between genotype and production system is therefore essential for understanding differences in egg production, egg quality, and overall performance (Usman et al., 2020).

Egg production is a complex trait composed of interrelated components. For example, egg mass is directly dependent on both egg number and individual egg weight (North & Bell, 1990; Bell & Weaver, 2002). Previous studies have demonstrated correlations between production traits, including strong positive relationships between body weight and egg weight, as well as between egg weight and reproductive parameters (Shahid et al., 2025). These relationships highlight the importance of applying appropriate statistical methods to distinguish biological effects from structural dependencies.

These methods enable a comprehensive assessment of the influence of genetic and environmental factors on poultry productivity.

The aim of the present study was to evaluate the effects of genetic origin and farm on egg production traits of Australorp laying hens under free-range conditions, and to analyse the relationship between laying intensity and average egg mass.

Materials and Methods

Data

The study was conducted on Black Australorp laying hens maintained under free-range housing conditions on two farms (KL and SM). In total, 47 hens were included in the study and distributed across farm and origin (rooster lines) and groups. The groups were established for practical breeding management purposes, as each group size corresponded to the number of hens that could be effectively mated by one rooster for subsequent research purposes. Therefore, the hen's group was not included as a separate factor in the further data analysis. (Table 1).

The study was conducted on hens hatched within a three-day window in January 2025, which commenced laying in late July 2025. Body weight was not assessed; however, no apparent differences in body

size were observed among the birds. All birds were reared under free-range housing conditions and monitored from the onset of lay until day 129 of production. The hens were maintained under relatively uniform feeding and management conditions, to the extent permitted by the free-range production system. While some environmental variability is unavoidable under free-range conditions, comparable husbandry practices were maintained across farms during the experimental period. Throughout the entire study period, the hens were fed a commercially manufactured complete feed mixture.

Table 1
Distribution of laying hens by farm and origin

Farm	Rooster	Hens	n
SM	David	D1	6
	David	D2	4
	Adisor	A1	6
	Adisor	A2	6
	David	D3	5
KL	David	D1	6
	Adisor	A1	7
	Adisor	A2	7

The dataset contained 1032 daily observations, including information on day of observation, farm, group, number of birds in the group, origin, total egg mass in the group, egg count in the group, average egg mass, and laying intensity. Data contained 44 missing values, resulting in 988 complete observations used in the data analysis.

The main response variable in the present analysis was laying intensity, expressed as the percentage of eggs produced relative to the number of hens in the group. In addition, average egg mass (g) was calculated from the total egg mass in each group and was analysed as a production trait.

The day of observation (day of laying) was used to create three biologically relevant observation periods: days 1–25, days 26–45, and days 46–129. These periods were defined to evaluate changes in laying performance over time and to compare production dynamics during the early, intermediate, and later phases of the laying cycle.

Data processing

Data processing and statistical analyses were performed in the R statistical environment (R Core Team, 2020), using the packages ggplot2 (Wickham, 2016), lmtest (Zeileis & Hothorn, 2002), dplyr (Wickham et al., 2023), and sandwich (Zeileis, 2004).

Initial data exploration was conducted using graphical methods. Barplot were used to visualize the distribution of laying intensity and average egg mass according to origin, farm, and observation period. Scatterplots with fitted linear regression lines were used to assess the relationship between laying intensity and average egg mass.

For descriptive presentation, mean values and standard errors were calculated for laying intensity and average egg mass within each farm, origin and period.

To evaluate the effects of genetic origin and farm in 3 observation periods on laying intensity and average egg mass two-way analysis of variance (ANOVA) was performed.

The relationship between laying intensity and average egg mass in 3 observation periods was evaluated using ANCOVA (Analysis of covariance). The model included farm as a factor, as well as the interaction between average egg mass and origin. The model follows:

$$laying\ intensity \sim average\ egg\ mass \times origin + farm$$

The assumptions of the fitted models were systematically evaluated.

For ANOVA and ANCOVA models, the normality of residuals was tested using the Shapiro–Wilk test, and the homogeneity of variances was assessed using Levene's test.

Because some models showed significant heteroscedasticity, heteroscedasticity-consistent robust standard errors (HC3) were additionally calculated for the main linear model of laying intensity using the sandwich and lmtest packages. This approach was used to confirm whether the main effects remained statistically significant after correcting for non-constant error variance.

The level of statistical significance was set at $\alpha = 0.05$. Differences and effects were considered statistically significant when $p < 0.05$.

Results and Discussion

Analysis of laying intensity and average egg mass

Research showed that overall laying intensity of the hens averaged 63.82% (SD 21.80) and egg mass averaged 55.99g (SD 6.24). Period-level means indicated a strong temporal pattern: laying intensity increased markedly from early to mid-period and then decreased slightly thereafter, whereas average egg mass increased monotonically across the three periods (Figure 1, Figure 2).

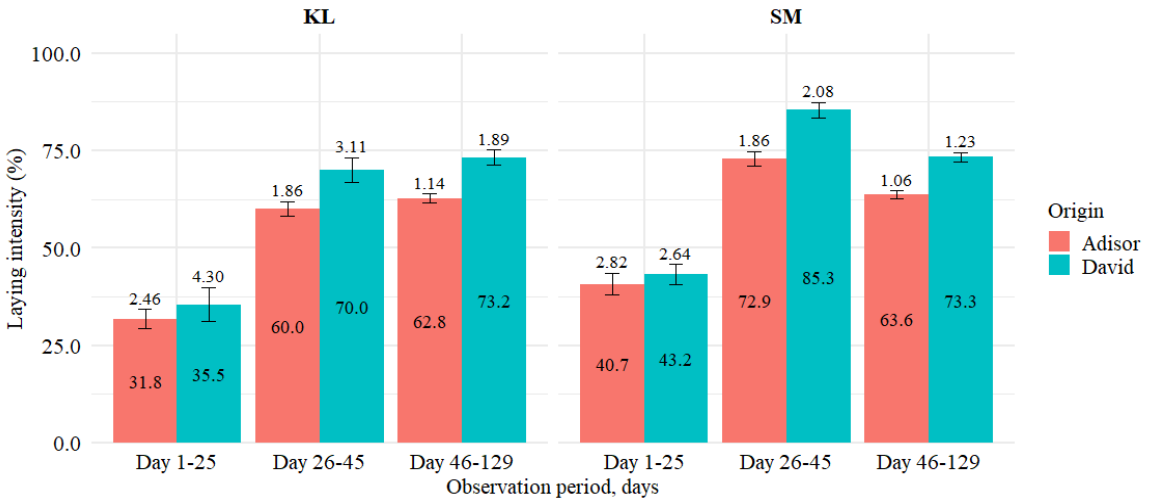
Figure 1 shows that laying intensity was lowest during days 1-25 across all groups (means ranging from 31.82% to 43.17%), increased sharply during days 26–45 (60.00% to 85.33%), and remained high during days 46–129 (62.76% to 73.21%). Average egg mass showed a consistent increase with time across all groups (Figure 2), rising from approximately 45.91–46.81 g during days 1–25 to 53.55–55.58 g during days 26–45 and to 58.06–59.91 g during days 46–129. Across periods and farms, David-origin hens tended to show higher laying intensity, while Adisor-origin hens tended to show higher average egg mass.

Within the early observation period (Day 1–25), laying intensity differed significantly between hens at different farms ($p<0.05$), with higher values observed in the SM farm, while no significant effect of origin was detected. In contrast, average egg mass did not differ significantly between either origin and farm in this period.

In the second observation period (Day 26–45), laying intensity was significantly affected by both origin and farm ($p<0.05$), indicating that both genetic and environmental factors contributed to differences among groups. For average egg mass, a significant effect of origin was observed ($p<0.05$), whereas farm had no significant influence.

In the final observation period (Day 46–129), laying intensity remained significantly influenced by origin ($p<0.05$), while no significant differences between farms were detected. A similar pattern was observed for average egg mass, where origin had a significant effect ($p<0.05$), but farm did not.

Overall, the results demonstrate that the significance of factors varied across observation periods. Farm-related differences were only evident in earlier stages, particularly for laying intensity, whereas origin consistently influenced both traits in later stages.



The observed increase in laying intensity from the initial period to later stages reflects the typical pattern of onset of lay, where egg production increases rapidly as hens approach peak production (Bain et al., 2016).

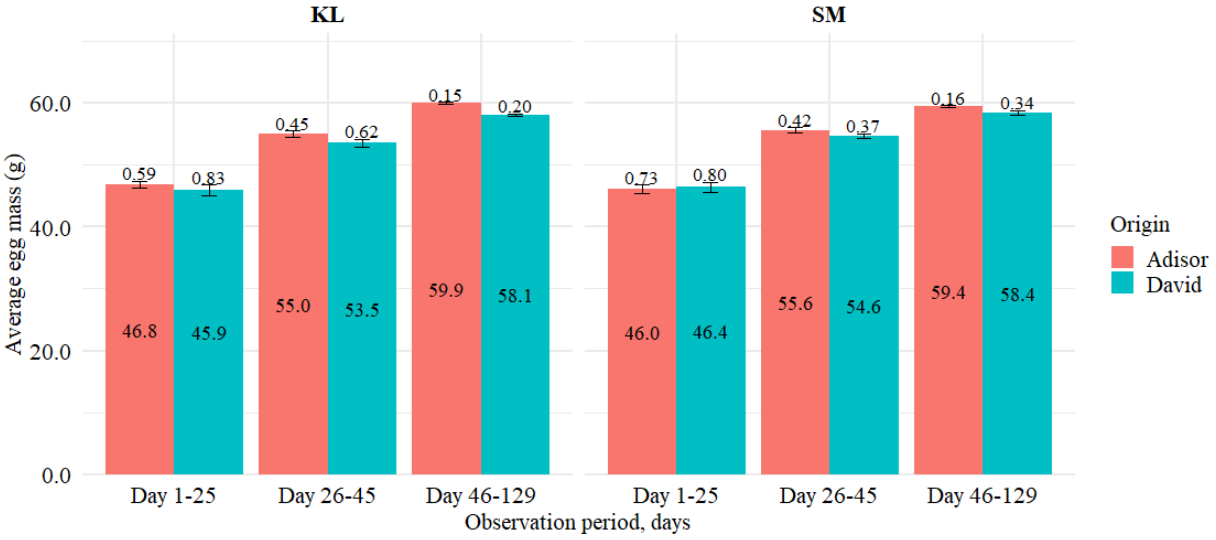
The increase in average egg mass with time is consistent with previous findings showing that egg weight increases with hen age due to physiological development and increased nutrient deposition (Johnston & Gous, 2007; Silversides & Scott, 2001).

The observed inverse tendency between laying intensity and egg mass suggests a trade-off between egg number and egg size, which has been widely reported in laying hens (Anang et al., 2000; Wolc et al., 2012).

Figure 1

The average egg-laying intensity of the hens (±SE) by period, farm, and origin

As we see (Figure 1), laying intensity peaked during days 26–45 for SM–David (85.33 ± 2.08; n = 60) and was lowest during days 1–25 for KL–Adisor (31.82 ± 2.62; n = 44), consistent with the strong period effect and higher David-origin values across periods. The dominant temporal structure is evident as a sharp increase from days 1–25 to days 26–45 followed by sustained high levels during days 46–129. This pattern reflects the typical egg production curve of laying hens, where production increases rapidly after the onset of lay and reaches peak levels before entering a phase of relatively stable production (Bain et al., 2016; Johnston & Gous, 2007).



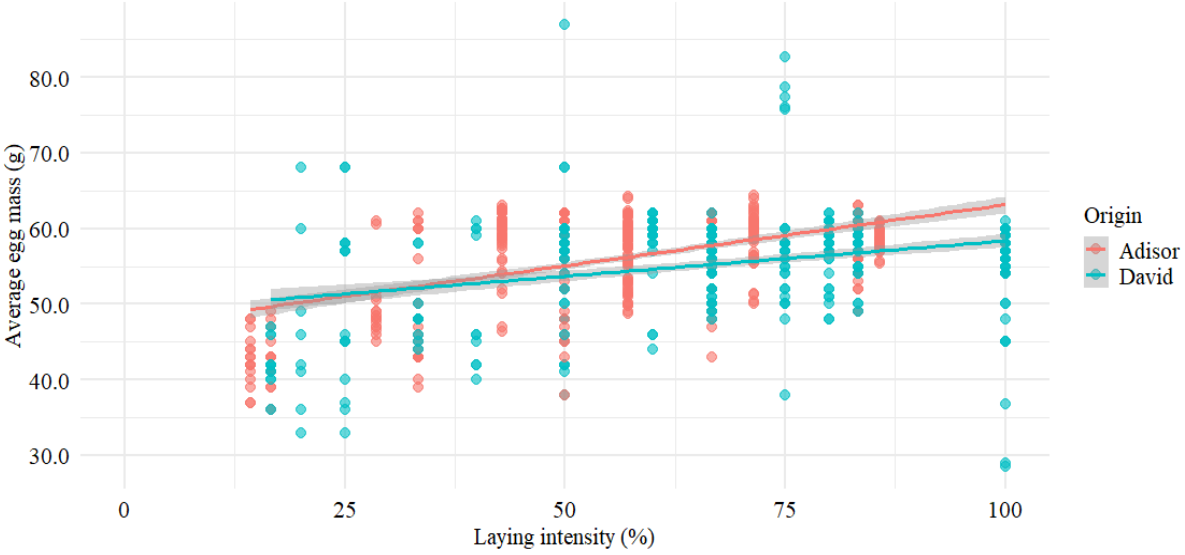
Within each farm and period, David generally exceeds Adisor ($p<0.05$), aligning with the significant origin main effect and the positive David–Adisor contrast. Such consistent differences between genetic lines are well documented, as egg production traits are strongly influenced by genotype, with substantial variation in laying intensity observed among different lines (Anang et al., 2000; Wolc et al., 2012). The higher performance of the David-origin birds, therefore, likely reflects genetic differences in production potential and resource allocation toward egg number.

Average egg mass for KL–Adisor increased from 46.81 ± 0.63 g (n = 44) from days 1–25 to 59.91 ± 0.15 g (n = 168) during days 46–129, illustrating a strong monotonic increase across periods (Figure 2). Across periods, Adisor tends to have higher egg mass than David (e.g., Day 46–129 in KL: 59.91 vs 58.06 g), consistent with the significant negative David − Adisor difference ($p<0.05$). The progressive increase in egg mass across periods is visually consistent across farms and origins. The modest but consistent separation between origins is also evident, with Adisor generally producing slightly heavier eggs ($p<0.05$).

The observed increase in egg mass with advancing production period agrees with previous studies demonstrating that egg weight increases as hens age due to continued development of the reproductive tract and increased deposition of egg components (Rizzi & Chiericato, 2005; Ledvinka et al., 2012). This age-related increase is primarily associated with enhanced albumen secretion and yolk deposition, resulting in progressively larger eggs over time (Molnár et al., 2016).

Figure 2

The average egg mass of the hens(±SE) by period, farm, and origin



The consistent differences between origins further support the role of genetic background in determining egg size. Genetic variation in egg weight among lines has been widely reported, with egg mass being a moderately to highly heritable trait influenced by selection history and breeding objectives (Zita et al., 2009; Wolc et al., 2012). The slightly higher egg mass observed in Adisor-origin birds therefore likely reflects genetic differences in allocation of resources toward egg size rather than egg number.

Relationship between laying intensity and average egg mass

The plotted trend (Figure 3) corresponds to a positive association between egg mass and laying intensity ($p<0.05$).

Figure 3

Relationship between hens laying intensity and average egg mass by origin

Although egg number and egg weight are often considered competing traits, previous studies have shown that their relationship may vary depending on genetic background and analytical approach. When environmental and temporal factors are accounted for, positive associations between egg mass and production traits can be observed, reflecting overall productivity of the hen (Lwelamira et al., 2009).

The positive slope reflects the statistically significant relationship between laying intensity and average egg mass after adjustment for farm and period. Similar relationships have been reported in genetic and phenotypic studies of laying hens, where production traits are influenced by both direct and correlated responses to selection, resulting in complex interactions between egg number, egg weight, and overall productivity (Mrode, 2005; Wolc et al., 2012).

Figure 4

Relationship between laying intensity and average egg mass stratified by observation period and origin

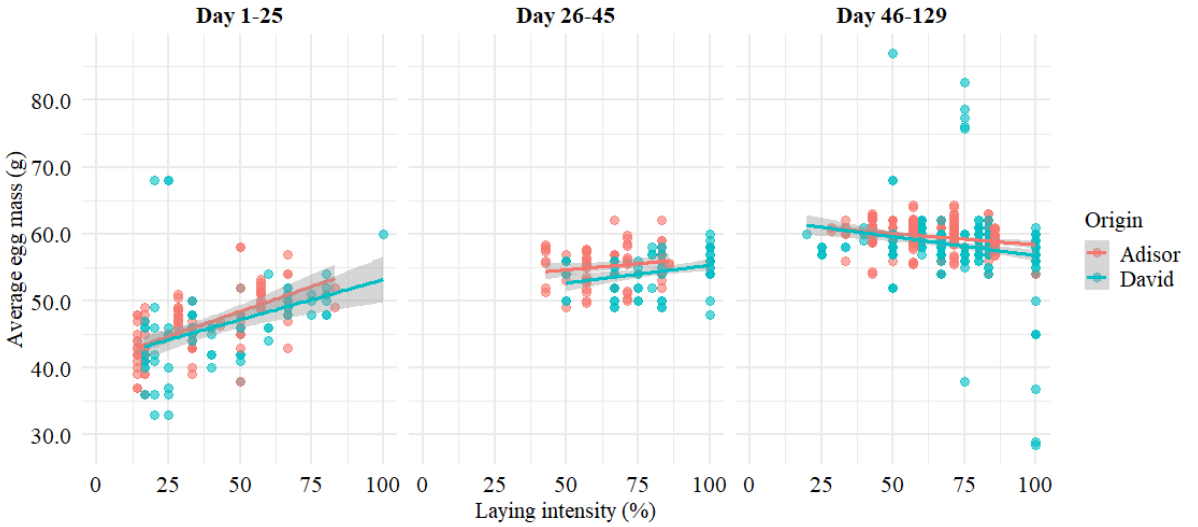


Figure 4 shows that the average egg mass–laying intensity relationship separately for days 1–25, days 26–45, and days 46–129, with regression lines and 95% confidence interval. This figure visualizes how the association pattern is embedded within the broader period structure highlighted in Figure 1 and Figure 2. The clear stratification by period reflects distinct physiological production states and supports the inferential finding that period is the dominant factor influencing both traits.

Australorp hens laying intensity was significantly influenced by origin, farm, and production period, with the observation period being the strongest determining factor ($p < 0.05$).

When the analysis was performed separately across observation periods, distinct patterns in the influence of origin and farm on laying intensity and average egg mass were observed. In the early period (Day 1–25), average egg mass was not significantly affected by either origin and farm, whereas laying intensity was significantly influenced by farm ($p<0.05$), indicating a stronger role of environmental conditions during the onset of lay. This is consistent with previous findings that early production is characterized by high variability and sensitivity to environmental and management conditions, as hens are still undergoing physiological adaptation to egg production (Bain et al., 2016; Roberts, 2004).

In the subsequent period (Day 26–45), both origin and farm significantly affected laying intensity ($p<0.05$), while average egg mass was influenced by origin only. This stage corresponds to the phase approaching peak production, where both genetic potential and environmental conditions contribute to performance variability (Anang et al., 2000; Wolc et al., 2012).

In the later period (Days 46–129), both traits were significantly affected by origin ($p<0.05$), whereas farm had no significant effect. This suggests that as production stabilizes, the influence of environmental variation decreases, and genetic differences become more consistently expressed. Similar patterns have been reported in laying hens, where the relative contribution of genetic factors increases as birds reach a stable production phase and environmental effects become less limiting (Bain et al., 2016; Zita et al., 2009).

These results can be explained by the progression of physiological adaptation from the onset of lay to a stabilized production state. During the early phase, incomplete physiological maturity and adaptation of the reproductive system result in greater variability and reduced expression of genetic differences (Roberts, 2004). As hens progress into a stable laying phase, biological systems become more regulated, allowing genetic potential to be more fully expressed and reducing the relative impact of environmental variation. Overall, the findings indicate that the relative importance of environmental and genetic factors shifts over time, with environmental effects being more pronounced during the initial phase and genetic effects becoming dominant as laying performance stabilizes. This temporal shift highlights the importance of considering the production stage when interpreting factors influencing laying performance.

Conclusions

1. The effects of farm and origin varied across production periods: farm significantly influenced laying intensity during the early and mid-production periods, whereas origin had a more pronounced effect during the mid- and late-production periods, particularly for laying intensity and egg.
2. Hens of David origin exhibited higher laying intensity, whereas Adisor hens produced slightly heavier eggs, indicating origin-related differences in productive performance under free-range conditions.
3. Both laying intensity and average egg mass increased throughout the observation period, with the highest laying intensity observed during the mid-production period (Day 26–45) and the greatest egg

mass during the late-production period (Day 46–129).
4. The effect of origin became more pronounced over time, significantly influencing both laying intensity and average egg mass in the mid- and late-production periods ($p<0.05$), indicating stronger expression of genetic differences as production stabilized.
5. A significant positive relationship between laying intensity and average egg mass was identified, indicating that higher productivity was associated with increased egg mass.

Abstract
Early-generation selection in spring wheat is constrained by limited seed availability, making rapid, high-throughput, and non-destructive phenotyping essential. The objective of this study was to determine the most informative vegetation indices (VIs) for predicting key agronomic traits, including plant number, spike number, productive tillering, and grain yield, to support early-generation selection in spring wheat breeding (F_4–F_5 generations) using UAV- based remote sensing. Seventeen breeding lines from three crossing combinations and six parental varieties were sown in three randomized replications at the AREI Stende Research Centre in 2025 using a cassette-type plot seeder. Two sowing variants were tested: 500 seeds m^{-2} and a fixed row-based seeding of 40 seeds per row. Plots consisted of three 1 m rows with 33 cm spacing, and the standard variety 'Arabella' was included as a reference control. Seven UAV flights were conducted from the seedling to late-milk growth stages using a DJI Matrice 300 RTK with a Sentera AGX710 multispectral camera. Orthomosaics were radiometrically calibrated, and bare soil pixels were excluded using index thresholds and supervised classification. Sixteen vegetation indices (7 RGB, 9 multispectral) and vegetation fraction were extracted per plot along with ground-truth measurements. Multicollinearity analysis identified a subset of non-redundant indices for further evaluation. Vegetation index–trait relationships were growth-stage dependent, with the strongest correlations from stem elongation to milk development. Spike number demonstrated the most consistent associations with vegetation indices. NDRE showed the most stable relationships across UAV flights, indicating the potential of multispectral UAV indices for indirect assessment of yield-related traits in early-generation wheat breeding.

Introduction

Wheat (*Triticum aestivum* L.) is one of the most important and widely cultivated crops worldwide. To meet the continuously increasing global demand for food, it is essential to improve cereal yield per unit area. Therefore, a key objective of wheat breeding programs is to develop high-yielding genotypes that outperform existing cultivars under specific environmental conditions while also exhibiting improved disease resistance, resilience to climate change, and high processing and nutritional quality (Stella et al., 2023).

Phenotyping of agronomic traits remains one of the major bottlenecks in modern crop breeding programs due to the large number of genotypes that must be evaluated under field conditions (Song et al., 2021). This challenge is particularly pronounced during early-generation selection, when seed availability is limited and field trials are often conducted in small plots or single rows with thousands of breeding lines under evaluation (Crain et al., 2022; Krause et al., 2020). Traditionally, breeders rely heavily on visual scoring to assess breeding lines, which is labor-intensive, time-consuming, and prone to subjective bias (Ninomiya, 2022). Improving the efficiency of early selection stages is therefore critical, as these stages aim to reduce the number of genotypes advanced to more resource-intensive yield trials and thereby increase genetic gain per unit cost (Fischer & Rebetzke, 2018; Hu et al., 2020).

Recent advances in remote sensing technologies have enabled high-throughput field phenotyping of crop traits, allowing rapid and non-destructive evaluation of large numbers of breeding lines (Feng et al., 2021; Gill et al., 2022). In particular, unmanned aerial vehicle (UAV) platforms equipped with imaging sensors provide high spatial and temporal resolution data that support efficient phenotyping in breeding trials.

RGB cameras are among the most widely used sensors in UAV-based crop phenotyping because of their high spatial resolution and relatively low cost. However, they capture reflectance only in three broad spectral bands (red, green, and blue), which limits the spectral information available for crop analysis. In contrast, multispectral sensors measure reflectance in several discrete wavelength bands, enabling more detailed assessment of crop physiological status. UAV-based multispectral remote sensing has shown considerable potential for crop monitoring, phenotyping, and yield estimation due to its high throughput, non-destructive nature, and ability to collect multi-temporal data over experimental fields (Liu et al., 2025a). Vegetation indices (VIs) derived from RGB and multispectral imagery are widely used as proxies for canopy greenness, biomass accumulation, and crop physiological status, including chlorophyll-related traits (Liu et al., 2025b; Wang et al., 2024; Zhang et al., 2024). Despite the increasing application of UAV-based remote sensing in crop monitoring and yield prediction studies, its use for early-generation selection in breeding programs remains relatively limited and insufficiently documented in the literature (Liu et al., 2025a). In early breeding generations, direct evaluation of yield-related traits is often constrained by small plot size and limited seed availability, which complicates the identification of promising genotypes. UAV-derived vegetation indices therefore represent a potentially valuable tool for

indirect assessment of agronomic traits during early selection stages. The objective of this study was to determine the most informative VIs for predicting key agronomic traits, including plant number, spike number, productive tillering, and grain yield, to support early-generation selection in spring wheat breeding (F_4–F_5 generations) using UAV- based remote sensing.

Materials and Methods

Plant materials

The plant material used in this study consisted of seventeen breeding lines derived from three crossing combinations and six parental spring wheat varieties. Detailed information on the evaluated genotypes is provided in Table 1.

Table 1

Spring wheat parental varieties and breeding lines used in the study

Cross	Parents	Breeding lines
1	Jasna × Mooni	F-019-0170/8, /9, /12, /13, /18, /29
2	Sorbas × Uffo	F-019-0174/37, /40, /44, /59, /69, /92
3	Bombona × K-15033	F-019-0203/101, /103, /117, /119, /122

For brevity, only the suffixes of breeding line numbers are shown in the table. Each set of lines within a cross share the same prefix.

Experimental design

The experiment was established as a randomized block design with three replications. Each genotype was represented by plots consisting of three 1 m rows, which served as the experimental unit for both field measurements and UAV-based analysis. Two sowing approaches were evaluated: a target density of 500 seeds m^{-2} and a fixed row-based seeding of 40 seeds per row. UAV-derived vegetation indices were extracted at the plot level and subsequently linked with ground-based measurements of agronomic traits.

Field trials were conducted at the AREI Stende Research Centre experimental site in northwestern Latvia (57°18′ N, 22°56′ E; WGS84) in 2025. The trials were sown on 17 April using a cassette-type experimental plot seeder. Each plot consisted of three 1 m rows with 33 cm row spacing, and the standard variety 'Arabella' was included as a reference control. Standard crop protection practices were applied. Herbicides were used according to local agronomic recommendations. At maturity, each row was harvested separately by cutting stems with a sickle, and the harvested material was subsequently threshed using a small-plot combine.

Measurement of agronomic traits

The evaluated agronomic traits included plant number (PN), spike number (SN), and grain yield (GY). Plant number per row was recorded at early growth stages on 12 May, while spike number per row was determined at maturity on 4 August. Grain samples from each row were cleaned using a Pfeuffer Sample Cleaner equipped with a 2.0 mm screen and subsequently weighed to determine grain yield per row, which was expressed as grams per row (g row^{-1}) based on a harvested row length of 1 m.

UAV data acquisition and processing

Images were acquired using a DJI Matrice 300 RTK unmanned aerial vehicle (UAV) equipped with a Sentera AGX710 multispectral camera capturing RGB, red-edge, and near-infrared (NIR) bands. All flights were conducted with a nadir (90°) camera orientation.

UAV data were acquired seven times during the growing season (Table 2). UAV flights were scheduled to capture the main wheat developmental stages throughout the growing season. Because slight differences in phenological development may occur among breeding lines, the Zadoks growth stage assigned to each flight represents the dominant crop stage observed across the experimental plots at the time of image acquisition. In total, 251 images were collected at an average flight altitude of approximately 20 m above ground level (AGL), resulting in a ground sampling distance (GSD) of 5.7 mm per pixel. Flights were conducted between 11:00 a.m. and 1:00 p.m. under near-clear sky conditions. The flight speed was set to 0.4 m s^{-1}, and both forward and side image overlap ratios were set to 75%.

Table 2

UAV flight dates and corresponding wheat growth stages during the 2025 growing season

Flight	Date	GS	Growing stage description
F1	13 May	12	Seedling stage
F2	26 May	25	Tillering
F3	10 June	32	Stem Elongation
F4	23 June	43	Booting
F5	9 July	65	Anthesis
F6	22 July	70	Early milk
F7	28 July	77	Late milk

Note: GS indicates the approximate Zadoks growth stage at the time of UAV flight.

Multispectral images were processed using Pix4DMapper Pro (Pix4D SA, Switzerland) to generate radiometrically calibrated reflectance orthomosaics. The orthomosaics were further processed in QGIS version 3.16 using multispectral bands (Red, Green, Blue, NIR, and Red-edge).

Vegetation was separated from soil using empirically defined NDVI thresholds. Pixels with NDVI ≤ 0.15 (sparse vegetation) or ≤ 0.25 (dense canopy) were classified as soil and masked as NoData to minimize soil background influence.

Experimental plots were delineated according to the field layout, and each plot was treated as a single sampling unit for vegetation index extraction using zonal statistics.

Based on a review of relevant literature, sixteen VIs widely used for assessing crop growth, yield, and biochemical parameters were calculated, including seven RGB-based and nine multispectral indices. The vegetation indices and their calculation formulas used in this study are presented in Table 3.

Table 3
List of spectral vegetation indices used in this study and formulas for their calculation

Index	Full name	Equation
RGB		
VARI	Visible Atmospherically Resistant Index	(g−r)/(g+r−b)
ExG	Excess Green Index	2*g−r−b
ExR	Excess red vegetation index	1.4*r − g
ExGR	Excess green minus excess red index	ExG-ExR
RGBVI	RGB Vegetation Index	$(g^2-(b*r))/(g^2+(b*r))$
GLI	Green Leaf Index	(2*g−r−b)/(2*g+r+b)
NGRDI	Normalized green-red difference index	(g−r)/(g+r)
Multispectral		
NDVI	Normalized Difference Vegetation Index	(NIR−R)/(NIR+R)
NDRE	Normalized Difference Red Edge Index	(NIR−RE)/(NIR+RE)
GNDVI	Green NDVI	(NIR−G)/(NIR+G)
RVI	Ratio vegetation index	NIR/R
EVI2	Two-band Enhanced Vegetation Index	2.5*(NIR-R) / (NIR + 2.4*R + 1)
MSR	Modified simple ratio red-edge	((NIR/Red) − 1) / (SQRT(NIR/Red) + 1)
MSAVI	Modified Soil-Adjusted Vegetation Index	(2*NIR+1-SQRT((2*NIR+1) ^2-8*(NIR-RED)))/2
SIPI	Structure insensitive pigment index	(NIR-B)/(NIR-R)
RDVI	Renormalized Difference Vegetation Index	(NIR-R)/SQRT(NIR+R)

Notes: R, G, and B denote reflectance values in the red, green, and blue bands, respectively; NIR denotes near-infrared reflectance and RE denotes red-edge reflectance. r, g, and b represent normalized RGB components calculated as r = R/(R+G+B), g = G/(R+G+B), and b = B/(R+G+B).

Statistical analysis

All statistical analyses were performed in Python using the Google Colab environment. Data processing and statistical computations were conducted using the libraries pandas, NumPy, and SciPy. Multicollinearity among vegetation indices was assessed separately for each flight using Pearson correlation matrices and hierarchical clustering; from each cluster, the index with the lowest mean absolute correlation was retained to reduce redundancy. Relationships between agronomic traits and vegetation indices were evaluated using Pearson's correlation analysis. Regression analysis was performed using linear mixed-effects models implemented in the statsmodels package. Data visualization was carried out using matplotlib and seaborn, including correlation heatmaps and dendrograms.

Results and Discussion

Selection of non-redundant vegetation indices

Multicollinearity analysis identified a subset of VIs with non-redundant spectral information across UAV flights and sowing variants (Table 4). Five RGB-based indices (VARI, ExGR, ExR, RGBVI, and GLI) and four multispectral indices (NDRE, GNDVI, SIPI, and RDVI) were selected for further analysis. Multicollinearity analysis is commonly applied in UAV-based crop monitoring studies to identify non-redundant predictors and improve the stability of statistical models (Zhang et al., 2025).

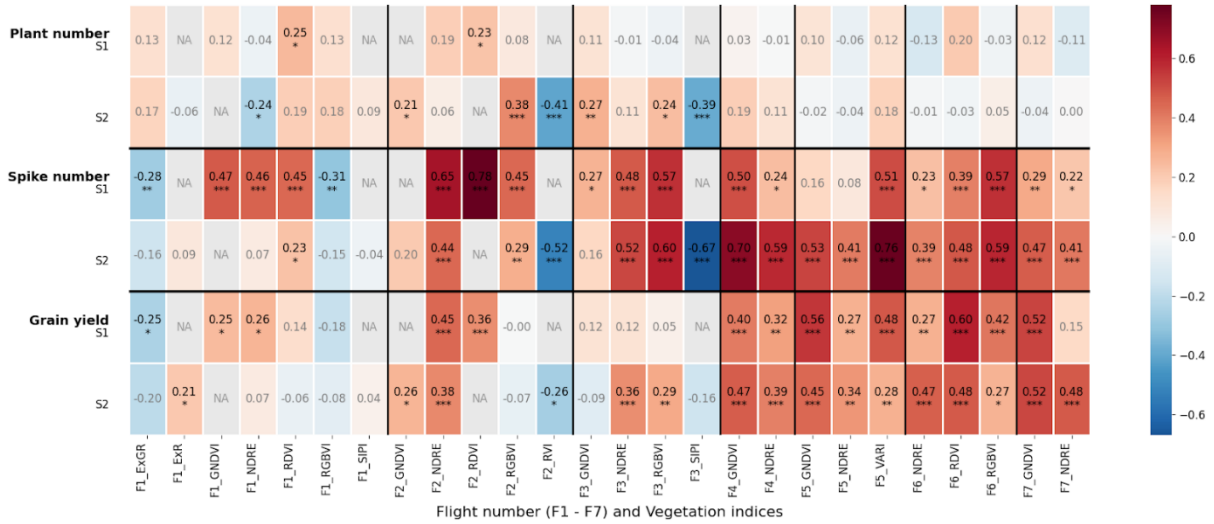
The composition of the selected VI set varied across flight dates and between sowing variants, indicating changes in complementary spectral information during crop development. Overall, multispectral indices were retained more consistently than RGB-based indices.

Table 4
Vegetation indices retained after multicollinearity analysis for each UAV flight and sowing variant

Vegetation indices	F1	F2	F3	F4	F5	F6	F7
VARI					●		
ExGR	○						
ExR	○●						
RGBVI	○●	○	○			○	
GLI	●	●	●			●	
NDRE	○●	○●	○●	○●	○●	○●	○●
GNDVI	○		○●	○●	○●		○●
SIPI	○●		○●				
RDVI	○●	○			○●	○●	

Notes: ○ – sowing variant 1 (500 seeds m^{-2}); ● – sowing variant 2 (40 seeds per row); F1–F7 – consecutive UAV flights during the growing season; Symbols indicate vegetation indices retained after multicollinearity screening; Abbreviations of vegetation indices are given in Table 3.

NDRE was selected across all UAV flights and both sowing variants, suggesting that the red-edge spectral region provides stable information throughout the growing season. Because red-edge reflectance is closely associated with chlorophyll concentration and canopy nitrogen status, NDRE may represent a robust indicator of crop physiological status in wheat breeding trials (Cao et al., 2021; Šušlikova et al., 2023). The stability of NDRE across both sowing variants further suggests that this index is relatively insensitive to differences in plant density and canopy structure.



GNDVI and RDVI were also frequently retained, indicating their relevance for capturing variations in canopy vigor and chlorophyll-related traits during crop development. In contrast, RGB-based indices showed greater variability across flight dates and sowing variants. RGB indices were most often retained during the early flights (F1–F2), when canopy cover was sparse and soil background influence was stronger, whereas multispectral indices became more dominant at later growth stages. These results suggest that combining RGB and multispectral vegetation indices may provide complementary information for UAV-based phenotyping across crop growth stages.

Correlations of agronomic traits with selected VIs across UAV flights and sowing variants

Clear relationships between vegetation indices and agronomic traits were observed across UAV flights, with the strongest and most consistent correlations detected for multispectral indices. These patterns are illustrated in the Pearson correlation heatmap shown in Figure 1. Overall, the most stable VI–trait relationships were observed for indices incorporating NIR and/or red-edge bands. This observation is consistent with previous studies showing that multispectral indices generally provide more robust associations with crop traits than RGB-based indices, although RGB indices may perform well at specific growth stages (Heinemann et al., 2025; Cao et al., 2021). In the present study, RGB indices also showed relatively strong correlations with agronomic traits at the stem elongation, anthesis, and early milk stages.

Figure 1

Pearson correlation heatmap between agronomic traits and selected vegetation indices across UAV flights (F1–F7) and sowing variants (S1–S2)

F1 - two-leaf stage (GS12); F2 - tillering (GS25); F3 - stem elongation (GS32); F4 - booting (GS43); F5 - anthesis (GS65); F6 - early milk (GS70); F7 - late milk (GS77).

Across the season, VI–trait associations were strongest from stem elongation to late milk stages (F3–F7), whereas relationships were generally weaker during the early seedling and tillering stages (F1–F2). This pattern agrees with previous UAV studies demonstrating that VI–trait relationships are strongly growth-stage dependent (Camenzind & Yu, 2024), indicating that the reliability of VI-based trait assessment increases as canopy development progresses.

Among the evaluated traits, spike number showed the strongest and most consistent correlations with vegetation indices. Significant correlations were observed from F3 to F7, corresponding to stem elongation, booting, anthesis, and milk development stages. For grain yield, significant correlations were mainly detected from F4 to F7 in both sowing variants, corresponding to the period from booting to late milk. These results align with previous studies reporting that wheat yield prediction accuracy typically peaks around flowering and early milk stages, when vegetative development (biomass accumulation and plant height) is largely completed (Camenzind & Yu, 2024; Chu et al., 2025; Liu et al., 2023; Prey et al., 2022).

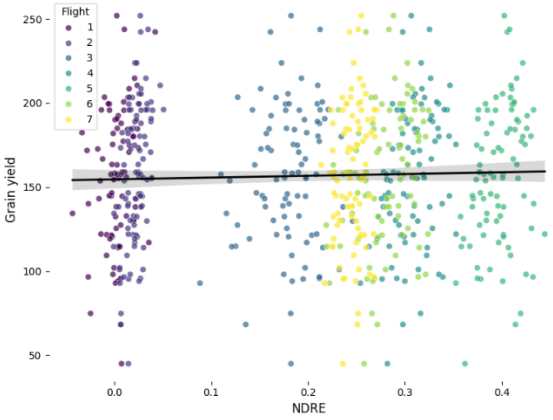
In contrast, plant number showed weak and inconsistent relationships with vegetation indices across the season (mostly $r < 0.3$), with only occasional moderate correlations at individual flights. This likely reflects the limited sensitivity of spectral indices to plant density after canopy closure, when spectral variation is primarily driven by canopy cover and

greenness rather than by the number of individual plants (Wilke et al., 2021). NDRE showed the most consistent correlations with spike number, particularly in sowing variant S2, where positive relationships were observed across multiple flights (F2–F7) with r values ranging from 0.39 to 0.59.

However, the highest single correlations in S2 were observed for VARI at F5 (r = 0.76) and GNDVI at F4 (r = 0.70). In sowing variant S1, spike number also showed strong positive associations, with the highest correlation observed for RDVI at F2 (r = 0.78). These results indicate that, although NDRE provided the most stable correlations across flights, individual RGB and multispectral indices occasionally showed stronger correlations at specific growth stages, consistent with previous studies showing that index performance depends on phenological stage (Camenzind &Yu, 2024; Heinemann et al., 2025).

VI–trait correlations also differed between the two sowing variants, indicating that sowing pattern influenced the spectral response of the crop canopy. In general, S2 showed stronger and more consistent correlations, especially for spike number, suggesting that canopy structure and plant density affected how effectively vegetation indices captured agronomic variation.

Taken together, these results indicate that multispectral VIs, particularly NDRE and GNDVI, were the most informative for assessing spike number and grain yield, especially from stem elongation to late milk stages.

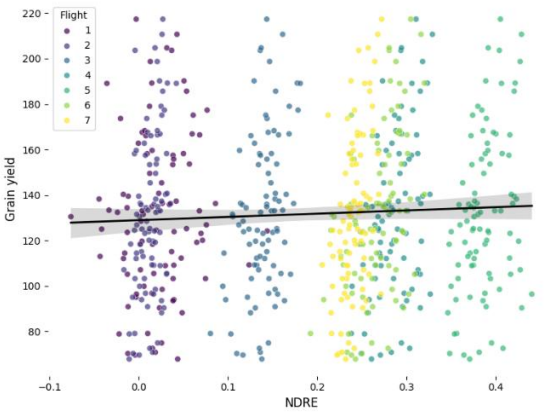


Relationship between NDRE and Grain Yield

Figures 2 and 3 show positive but weak mixed-effects relationships between NDRE and grain yield across seven UAV flights during the 2025 growing season for sowing variants 1 and 2. For both sowing variants, the fitted trend lines indicated a positive association between NDRE and grain yield, with higher NDRE values generally corresponding to higher final grain yield. This tendency was observed in both S1 and S2, although the wide dispersion of data points indicates substantial variability among plots. In both models, the NDRE effect was statistically significant ($p < 0.001$), indicating that higher NDRE values were associated with higher final grain yield.

These results support the correlation analysis presented in Figure 1, where NDRE showed stable associations with spike number and grain yield across multiple growth stages. The relationship is biologically plausible because NDRE reflects canopy chlorophyll status and green canopy vigor, both of which are closely related to crop productivity. Red-edge indices are particularly valuable in wheat because the red-edge spectral region is sensitive to chlorophyll concentration and generally less prone to saturation than red-based indices under dense canopy conditions (Cao et al., 2021; Liu et al., 2022). Similar findings have been reported in UAV-based wheat studies, where red-edge and multi-temporal vegetation indices demonstrated good potential for grain-yield estimation (Camenzind & Yu, 2024; Liu et al., 2023).

Figure 2



Mixed-effects regression between NDRE and grain yield (g row^{-1}) across all UAV flights for sowing variant 1

Despite the significant relationship, the relatively large scatter of observations around the fitted trend lines indicates that NDRE explains only part of the yield variability. This is expected because grain yield is a complex trait influenced by multiple interacting factors, including crop phenology, genotype differences, and environmental conditions (Liu et al., 2022; Mankin et al., 2024). The visible grouping of observations by UAV flight also suggests that temporal variation across growth stages contributed to the observed pattern. The visible grouping of observations by UAV flight also suggests that temporal variation across growth stages contributed to the observed pattern.

Figure 3

Mixed-effects regression between NDRE and grain yield (g row^{-1}) across all UAV flights for sowing variant 2

Previous studies similarly report that multi-temporal UAV observations generally improve wheat yield estimation compared with single- date imagery

(Camenzind & Yu, 2024; Liu et al., 2023). Overall, the consistent positive relationship observed in both sowing variants indicates that NDRE can serve as a useful indirect indicator of yield-related performance in early-generation wheat breeding trials.

Conclusions

1. Multicollinearity analysis identified a limited subset of non-redundant vegetation indices, among which NDRE, GNDVI, and RDVI were most consistently retained across UAV flights and sowing variants.
2. Vegetation index–trait relationships were strongly growth-stage dependent, with the strongest correlations observed from stem elongation to late milk stages, while relationships were weaker during early canopy development.
3. Among the evaluated agronomic traits, spike number showed the strongest and most consistent correlations with vegetation indices, whereas plant number exhibited weak relationships across the growing season.
4. NDRE showed the most stable associations with spike number and grain yield across UAV flights, and mixed-effects regression confirmed a significant positive relationship between NDRE and grain yield in both sowing variants, highlighting the potential of red-edge–based indices for UAV-assisted phenotyping in early-generation wheat breeding.

Abstract
Potato early blight is caused by several species of the genus *Alternaria*, but information about the spectrum of species involved remains limited. This study investigated the pathogenicity on potato leaves of two *Alternaria* species that cause early blight, as well as their antagonistic interactions with a *Bacillus subtilis*-based biological product under *in vitro* conditions. Fungal isolates – *A. solani* and *A. protenta* were obtained from the pathogen collection (collected from tomatoes) of the Institute of Soil and Plant Sciences and both are identified as *Alternaria* species that cause potato early blight. Antagonism assays showed that the inhibitory effect of *B. subtilis* depended on the application method: mycelial growth was strongly reduced when the medium was rinsed with the preparation, whereas only minor effects were observed when the bacterium was applied separately from the fungal inoculum. Pathogenicity assays demonstrated significant species-related differences in lesion development ($p < 0.05$), with *A. protenta* producing larger lesions than *A. solani*. Although the concentration and timing of *B. subtilis* application did not significantly affect lesion size, a tenfold higher concentration reduced lesion area by approximately 1.5 times. Comparing the species, *A. solani* showed a higher mycelial growth rate on PDA compared with *A. protenta*, with faster growth occurring during the first seven days post-inoculation. Overall, the results highlight species-specific differences in pathogenicity and a partial inhibitory effect of *B. subtilis*.
Keywords: antagonism, *A. solani*, *A. protenta*, biological control, early blight.

Introduction

In recent years, developed countries have tended to reduce their potato growing areas while substantially increasing processing activities. However, farmers continue to face daily challenges posed by potato diseases. Growing high-yield, high-quality potatoes without the use of plant protection products (PPP) against diseases and pests is practically impossible in both biological and integrated growing systems. Therefore, biologically based PPP containing various beneficial fungi and / or bacteria for plants, may offer a promising alternative to chemical PPP, potentially leading to improved yields.

The two most common and widespread foliar diseases affecting potatoes are early blight (caused by *Alternaria* spp.) and late blight (caused by *Phytophthora infestans*). Both of these diseases are observed together in potato fields every year. However, early blight has received limited study under the specific environmental conditions of Latvia.

Potato early blight is caused by fungi of the genus *Alternaria*. The pathogen belongs to the *Ascomycota* phylum, *Pleosporales* order. The genera of *Alternaria* are currently divided into 29 sections – *Porri*, *Alternaria*, *Ulocladioides*, and *Infectoriae* etc., encompassing numerous species with varying ecological roles, ranging from highly aggressive plant pathogens to weakly pathogenic or non-pathogenic. Taxonomic revisions are still in progress (Ahmadpour et al., 2025; Schmey et al., 2024; Vinogradova et al., 2026). *Alternaria* contains melanin in the cell walls of both hyphae and conidia. This melanin contributes to increased cell wall rigidity, enhancing resistance to antifungal agents. Moreover, this adaptive capacity enhances the pathogen's ability to survive overwintering conditions (Fernandes et al., 2021; Schmey et al., 2024).

Alternaria species can infect a wide range of host plants across multiple families, including but not limited to *Solanaceae* (Bessadat et al., 2014; Dučkena et al., 2024, 2019; Gou et al., 2023; Ivanović et al., 2022). Until recently, only two *Alternaria* species – *A. solani* and *A. alternata* were reported in potato crops. *A. protenta* (Woudenberg et al., 2014) and *A. grandis* (Rodrigues et al., 2010) were also identified as potentially harmful to potatoes (Landschoot et al., 2017). *A. protenta* was initially identified as a pathogen affecting *Helianthus annuus*, but more recently it has been recognized as an *Alternaria* species capable of causing early blight in potatoes (Cho & Yu, 2000; Ivanović et al., 2022).

The host range of *A. protenta* has significantly expanded and now includes plant species from the *Asteraceae*, *Gramineae*, and *Solanaceae* families. Due to their close morphological and molecular similarity, *A. protenta* and *A. solani* can be accurately differentiated only by locus sequencing (Woudenberg et al., 2014). Recent collections of isolates from the Mediterranean region have revealed that the species *A. protenta* can also be isolated from potato leaves (Bessadat et al., 2019). A study conducted in Russia also identified *A. protenta* as one of the most prevalent *Alternaria* species in potato fields. The isolates were collected from both the Far Eastern and European regions of the country (Kokaeva et al., 2022). In a long-term study carried out in Serbia, *Alternaria solani*, *A. protenta*, *A. grandis*, and *A. linariae* were isolated from potato foliage (Ivanović et al., 2022).

Potato plants are resistant to early blight at juvenile stages, but susceptibility increases with plant age (Yuldashova et al., 2023). Despite the lack of observed sexual reproduction, high species diversity indicates pathogen recombination (Schmey et al., 2024; Tsedaley, 2014).

Pathogens survive and overwinter in plant debris, soil, and potato tubers as mycelium or conidia, and their spores are disseminated by wind, water, and occasionally insects (Chaudhary et al., 2021; Tsedaley, 2014; Yuldashova et al., 2023). These pathogens reproduce asexually via conidia. In spring, conidia spread from infected plant debris to lower leaves and germinate, followed by mycelial growth on infected tissues. Conidiophores are formed at night under humid conditions, while conidia develop during the subsequent dry daylight conditions, and reach full maturity by the next humid night (Tsedaley, 2014). Warm, humid conditions promote pathogen development, with rapid conidial formation at 20–30 °C, especially under relative humidity below 70% (Escuredo et al., 2019; Tsedaley, 2014).

Alternaria spp. symptoms mainly involve leaf spotting appearing on mature lower leaves before or during flowering, around 37–40 days after emergence (Chaudhary et al., 2021; Meno et al., 2022; Tsedaley, 2014). Lesions appear as large brown necrotic areas with concentric yellow rings or as numerous small brown to black spots, and infected leaves may dry out and remain attached or fall off (Schmey et al., 2024). Lesions differ among species: *A. grandis* and *A. linariae* produce small dark concentric rings, *A. solani* forms large dark spots, and *A. protenta* causes light to dark brown spots (Ivanović et al., 2022). Pathogen also infects stems and tubers (Chaudhary et al., 2021; Tsedaley, 2014).

Beneficial bacteria and fungi can support biological and sustainable farming. Microbiological products containing bioagents like *Trichoderma* spp. and *Bacillus* spp. are most commonly mentioned in experiments and scientific literature.

Genus *Bacillus* belongs to the kingdom *Bacteria*, class *Bacilli*, family *Bacillaceae*. It is a gram-positive, rod-shaped, aerobic and motile bacteria. These bacterial species include both beneficial and pathogenic members, ranging from plant growth-promoting and disease-suppressing bacteria to highly pathogenic species with severe or lethal effects in humans (for example, *B. anthracis*, which causes anthrax) (Khan et al., 2022; Tam et al., 2006). *Bacillus* spp. is one of the most widespread rhizobacteria used in agriculture, with *B. subtilis* being the best-known species.

These rhizobacteria support plant health by: releasing volatile compounds that stimulate root exudation; producing antibiotic secondary metabolites, and; forming protective biofilms on roots that shield them from harmful organisms, and help them attach more easily to substrates and further increase their survival abilities; form endospores, which play a significant role in enhancing their survival capabilities (Choudhary & Johri, 2009; Khan et al., 2022).

Previous studies have demonstrated the potential of *Bacillus* species in potato disease management. Foliar application of *B. subtilis* spores has been shown to reduce the incidence of black scurf (caused by *Rhizoctonia solani*) and common scurf (caused by *Streptomyces* spp.). Several studies also report the effectiveness of *B. subtilis* against *Phytophthora infestans*, as well as improvements in plant physiological traits. In addition, treatment of potato mini-tubers with *Bacillus* strains has been shown to reduce disease incidence under laboratory conditions, while *B. velezensis* has demonstrated in vitro activity against *R. solani* and *Fusarium* spp. (Choudhary & Johri, 2009; Kumar et al., 2013; Kumbar et al., 2019; Lastochkina et al., 2022; Wei et al., 2024).

Therefore, there is a reason to believe that biological plant protection – using preparations containing non-pathogenic fungi and bacteria – cannot only enhance plant resistance to pathogens but also lead to an increase in yield. The aim of this study was to evaluate the pathogenicity of *Alternaria solani* and *A. protenta* on potato leaves and their antagonistic interactions with a *Bacillus subtilis*-based biological product (strain MSCL 1441).

Materials and Methods

Pathogen isolates

The study used two *Alternaria* spp. isolates – *A. solani* LD187 and *A. protenta* LD008. These isolates were obtained from the collection of the Institute of Soil and Plant Sciences. For pathogenicity and antagonism tests, the isolates used were from the second passage, 14 days after inoculation on PDA (potato dextrose agar) media.

Antagonism test

Preparation is based on a microbiological product containing the bacterial strain *Bacillus subtilis* MSCL 1441, which was isolated from Latvian soil and provided by the Latvian State Institute of Wood Chemistry. In this experiment, the antagonism between the *B. subtilis*-based preparation and two *Alternaria* isolates was examined under *in vitro* conditions on PDA plates. For this assay, the preparation was applied without dilution. Antagonistic activity was assessed under different setups: when both organisms were placed on the plate simultaneously; when *B. subtilis* was introduced first and the *Alternaria* isolates added later; and when plates were rinsed with the *Bacillus* preparation before placing the *Alternaria* mycelial discs.

Positive and negative controls were established using either sterile PDA discs or mycelial discs of the fungal isolates. Sterile PDA discs served as negative controls to verify the absence of contamination or external factors, while mycelial discs of the pathogens were used as positive controls to confirm their ability to colonize the medium.

All Petri dishes were sealed with cling film to maintain sterility.

Pathogenicity test

The pathogenicity of two Alternaria isolates was evaluated based on their ability to infect potato leaves under different in vitro conditions. *Bacillus subtilis* preparation was tested at two different concentrations (1.5×10^{12} CFU mL^{-1}; 1.5×10^{13} CFU mL^{-1}) and at

two different treatment times (treatment one day before inoculation and treatment one day after inoculation).

Initially, under laboratory conditions, Pre-basic Tissue Culture (PBTC) minituber category seed potatoes of the cultivar 'Madara' were grown in pots. Seed tubers were planted in pots containing a universal garden peat substrate. One month after planting, leaves of the same age (from the 3rd–4th leaf level) counted from the base of the plant, were selected for the experiment. Metal trays (450 × 300 × 50 mm) were surface-disinfected with 96% ethanol and air-dried. Two layers of filter paper were placed inside each tray, followed by the addition of 100 mL of sterile distilled water. Two disinfected glass rods (280 mm long) were placed in each tray, and the potato leaves were arranged on them, so that they did not come into contact with the moist filter paper.

Similar to the morphological description, 5 mm PDA or mycelial discs were obtained using a cork borer and transferred onto the leaves with a metal needle, ensuring direct contact between the mycelial disc and the potato leaf. The mycelial discs were positioned at the center of each leaf. As a positive control, *Alternaria* isolates were used to confirm the ability to cause infection, whereas sterile PDA discs were placed on the potato leaves and served as the negative control. In Variant A, *Alternaria* isolates were applied first to the potato leaves, and the following day, the leaves were sprayed with the *B. subtilis* preparation at two different concentrations. In Variant B, the leaves were first sprayed with the preparation (at the same two concentrations), and inoculation with the isolates was carried out 24 hours later. Each variant was performed in four replicates.

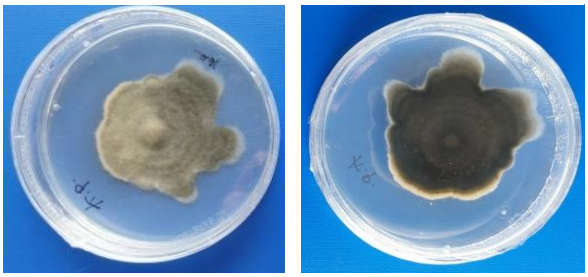
The metal trays were covered with cling film (plastic wrap) to maintain moisture and ensure optimal conditions for fungal development. The metal trays were maintained at +20 °C. After 144 hours (6 days) from the first inoculation, the diameter of the lesions formed by the mycelium was measured (two measurements – at the widest and narrowest points, expressed as the average value).

Data analysis

To determine the significance of the results obtained in the pathogenicity test, a one-way analysis of variance ANOVA was performed using the R software. Significance was assessed at the $p \leq 0.05$ level. In cases where differences were statistically significant, the LSD and Bonferroni post hoc tests were performed.

Results and Discussion

Colony morphology



Visual photographs of the colonies were taken on day seven after inoculation (Figure 1). *Alternaria protenta* (LD008) formed olive-grey to dark-grey colonies with cottony mycelium. The colony expanded evenly and developed distinct concentric rings of lighter and darker shades around the initial mycelium. Colony elevation was generally flat, slightly raised in the center, with smooth, rounded margins and light grey to white edges. No visible pigmentation of the medium was observed. Similar colony colour and morphology of *A. protenta* have been reported in previous studies (Bessadat et al., 2019; Cho & Yu, 2000).

In contrast, *Alternaria solani* (LD187) formed slightly greenish-yellow colonies with cottony mycelium and similar concentric zonation. The colonies were also flat with smooth margins, but a light-yellow pigmentation of the medium was observed. Previous studies report that *A. solani* may exhibit yellowish pigmentation and morphological variability among isolates (Bessadat et al., 2019; Kumar et al., 2008).

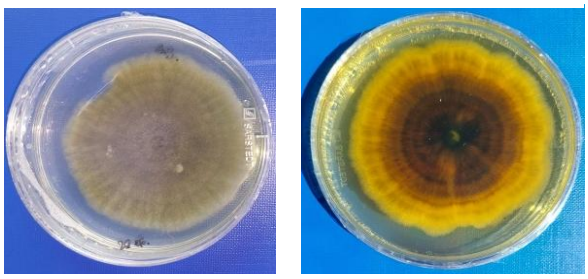


Figure 1

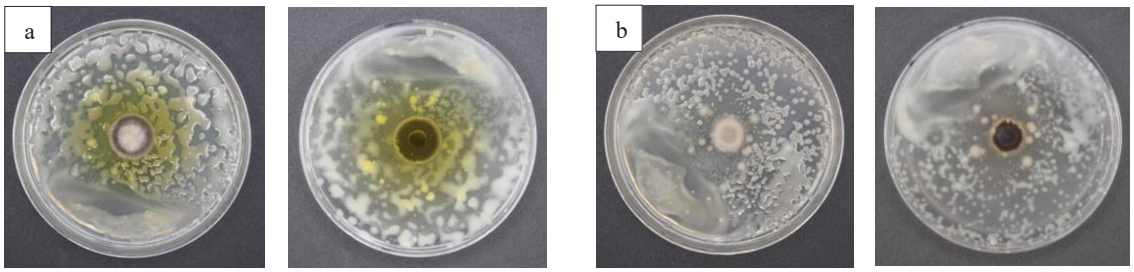
Colony morphology of Alternaria isolates A. protenta and A. solani (left: upper surface; right: lower surface)

A. protenta

A. solani

Comparison of the isolates showed that *A. solani* isolate demonstrated a higher growth rate compared to the *A. protenta* isolate. Both isolates grew faster up to seven days after inoculation, after which their growth rate declined. However, *A. solani* isolates from different locations may vary in mycelial growth rate and can also differ markedly in their morphological characteristics (Kumar et al., 2008; Marak et al., 2014; Nikam et al., 2015).

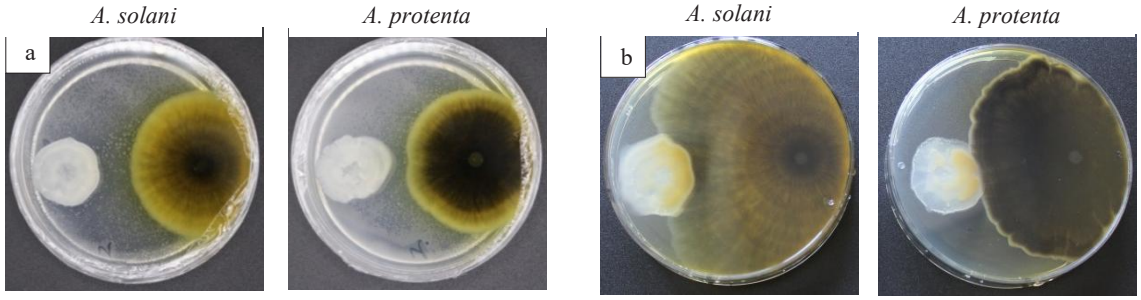
Antagonism test



After 7 days, antagonism was observed in all variants, except where *Alternaria* isolates were applied after 10 days and antagonism was evaluated one week later.

Both self-pairings of *Alternaria* isolate and the interactions between the two isolates were compatible, with no visible demarcation line observed at the contact interface.

In the treatment where the Petri dish was rinsed with the *Bacillus* spp. preparation and subsequently inoculated with a mycelial disc placed at the center, mycelial growth was initiated but progressed very slowly (Figure 2). Compared with the negative control



(pathogen inoculated on PDA medium only) colony expansion was markedly suppressed, and further radial growth was almost completely arrested. The colonies appeared compact, and the mycelium did not spread beyond the initial inoculation site, creating the appearance of an inhibition zone in which the mycelium seemed encapsulated around the inoculated disc.

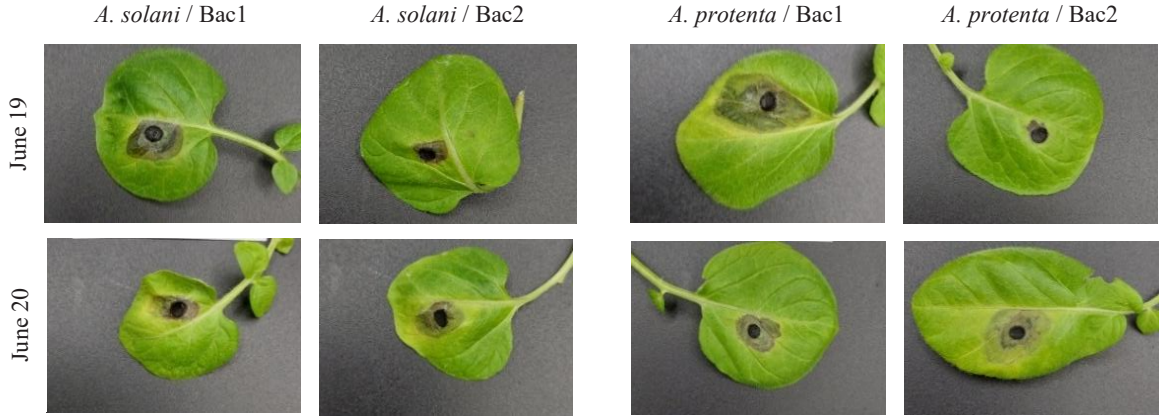
Figure 2
Evaluation of antagonistic activity on PDA medium rinsed with a Bacillus subtilis preparation.
Left – top view of Petri plate, right – bottom view: a – mycelial disc of A. solani; b – mycelial disc of A. protenta

A different experimental variant was performed, in which a drop of the *B. subtilis* preparation was applied to the medium, and the plate was sealed to promote bacterial growth. After seven days, an *Alternaria* isolate was inoculated on the opposite side (Figure 3). Both organisms showed visible growth. Although visible *B. subtilis* growth was observed, the pathogenic isolates also grew relatively rapidly once transferred onto the Petri plate. Images taken five days later showed that the fungal colonies appeared substantially larger than the *B. subtilis* colony, whereas the bacterial inoculum remained relatively small (Figure 3a). A subsequent set of photographs taken one week later (after 19 days from start) revealed that the fungal mycelium eventually suppressed *B. subtilis* growth, with no demarcation line observed at the contact zone (Figure 3b).

Figure 3
Antagonistic interactions between B. subtilis and Alternaria isolates on PDA medium:
a – five days after inoculation with fungal isolates; b – one week later

It becomes evident that when a drop of *B. subtilis* is applied one week prior to the pathogen mycelium, it grows more extensively, forming a larger colony and experiencing less restriction compared to the situation where both antagonists are introduced simultaneously. The growth patterns of both organisms on PDA medium illustrate their interaction dynamics. In similar studies, *Bacillus* spp. have exhibited antagonistic activity both *in vitro* and *in vivo* against *Alternaria* species associated with tomato early blight (Matar et al., 2009; Pane & Zaccardelli, 2015).
B. subtilis demonstrated strong inhibitory properties in the treatment where the Petri dish surface was rinsed with the preparation. It can be assumed that when the surface is saturated with *B. subtilis*, there is insufficient space or resources for the competing organism to grow. In contrast, in the treatment where a drop of *B. subtilis* was placed opposite the pathogen isolates, a slight reduction in the radial growth of the mycelium was observed, but the pathogen was not completely suppressed. Furthermore, *B. subtilis* did not develop as rapidly as the *Alternaria*, which allowed the latter to continue spreading.

Pathogenicity test



The experiment involved two *Alternaria* isolates – *A. protenta* and *A. solani* and potato cultivar 'Madara'. Three days after inoculation (DAI), mycelial growth was observed in both isolates originating from the inoculated discs, indicating the onset of infection.
Six DAI, lesion diameter of the *A. solani* isolate ranged from 6 to 12 mm, whereas the lesions formed by the *A. protenta* isolate on potato leaves ranged from 6 to 31 mm, depending on the treatment variant (Figure 4). Symptoms observed on the leaves at six DAI in both cases were typical of potato early blight. Necrotic, dark brown lesions developed at the inoculation sites,

followed by the formation of yellow concentric rings around the necrotic tissue. In some treatment variants for both isolates, further infection was also observed, appearing as scattered small spots on the leaf surfaces.

Figure 4

Impact of application timing and concentration of Bacillus subtilis on the severity of Alternaria infection in potato foliage.

Potato leaves inoculated with Alternaria solani (right) and A. protenta (left). The top row shows leaves treated with a Bacillus subtilis preparation one day prior to inoculation, while the bottom row shows leaves inoculated first and treated the following day. Bac1: 1.5 × 10¹² CFU mL⁻¹; Bac2: 10-fold higher concentration

Statistical analysis showed that species had a significant effect ($p < 0.05$) on the growing rate of infection.

On average, *A. protenta* formed larger lesions in diameter than *A. solani*. In contrast, the concentration of the *B. subtilis* preparation and the timing of its application had no statistically significant effect on lesion development. Although the concentration of the preparation did not show a statistically significant effect on lesion diameter, the obtained p-value ($p = 0.054$) corresponds to a confidence level of 94.6%. The diameter of the infected lesions was 1.5 times smaller when using the 10-fold higher concentration of the *B. subtilis* preparation compared to the lower concentration. In a similar study by Baltzakis et al. (2025) on detached potato leaves, different *Alternaria* species were compared for their pathogenicity. *A. solani* and *A. protenta* both caused significant lesion development. In our study, *A. protenta* produced larger lesions, whereas in the study referenced above, *A. solani* was reported as the more aggressive species in terms of lesion size. It should be noted that Baltzakis et al. (2025) used isolates originating from potato fields and inoculation was performed using a spore suspension.

Conclusions

1. *B. subtilis* exhibited strong inhibitory effects when the Petri plate surface was thoroughly rinsed with the preparation, likely limiting space and resources for the competing pathogen. In contrast, when a drop of *B. subtilis* was applied opposite the pathogen isolates, only a slight reduction in mycelial radial growth was observed, and the pathogen was not completely suppressed.
2. Statistical analysis indicated that the isolate species significantly influenced growing rate ($p < 0.05$). On average, *A. protenta* produced larger lesions than *A. solani.*
3. In contrast, neither the concentration nor the timing of application of the *B. subtilis* preparation had a statistically significant effect on lesion development.

Acknowledgements

The research was supported by the AREI project 'Evaluation of the interaction between the potato early blight pathogen *Alternaria* spp. and the microbiological preparation *Bacillus subtilis* MSCL 1441 isolate under *in vitro* conditions'.

The authors are grateful to the Latvian State Institute of Wood Chemistry for providing the microbiological product and Lilija Dučkena for kindly providing the fungal isolates used in this study.

A REVIEW: THE INFLUENCE OF VARIOUS FACTORS ON THE COMPOSITION OF STARCH IN POTATO TUBERS

Abstract
Potato (*Solanum tuberosum* L.) starch is one of the main components of potato tubers, accounting for approximately 75% of tuber dry weight, and plays an important role in determining tuber quality, nutritional value, and processing properties. Potato starch primarily consists of amylose (AM) and amylopectin (AP), and the ratio between these polymers influences starch functionality, digestibility, gelatinisation behaviour, and glycaemic response. Higher amylose content (AMC) is associated with increased resistant starch formation, slower digestion, and reduced starch hydrolysis. However, most commercially cultivated potato varieties produce starch rich in amylopectin. This review summarises current knowledge on factors influencing potato starch composition and quality, with particular emphasis on AMC variation. The analysed studies demonstrated that genetic background is one of the main factors affecting starch-related traits, including starch composition, AMC, and granule structure. Environmental factors such as temperature, altitude, location, and seasonal variability may also influence starch synthesis and accumulation, often through genotype × environment interactions. In addition, tuber developmental stage, agronomic practices, and post-harvest storage conditions can modify starch composition and physicochemical properties. Recent studies have increasingly focused on relationships between starch molecular structure, AMC, and functional properties important for food and industrial applications. Nevertheless, the effects of environmental and agronomic factors reported across studies are not always consistent, indicating the need for further research on the combined influence of genotype, growing conditions, and crop management on potato starch quality.
Keywords: potato, starch, starch composition, amylose content, factors affecting starch composition.

Introduction

The potato is one of the most widely cultivated crops in the world and represents an important component of human nutrition. Compared with many other staple crops, potatoes provide a favourable nutritional profile, including a higher protein-to-carbohydrate ratio than most cereals and other root and tuber crops. Potato proteins contain a well-balanced composition of essential amino acids important for human nutrition. Potatoes are also an important source of dietary energy and provide valuable micronutrients. Due to their nutritional value and versatility in food preparation, potatoes can be considered an important component of a balanced and healthy diet alongside vegetables and whole-grain foods (Niederhauser, 1993; Bamberg & del Rio, 2005; Camire et al., 2009; McGill et al., 2013; Visvanathan et al., 2015; Devaux et al., 2021).

Potatoes have a wide range of applications and are consumed in various forms worldwide. They are used both as fresh produce and as processed products, including semi-finished products and snack foods such as chips. Beyond their role in human nutrition, potatoes and potato starch also have broad applications in several industries, including food processing, cosmetics, pharmaceuticals, and other industrial sectors (Dupuis, & Liu, 2019).

Carbohydrates are the main nutritional component of potato tubers, with starch representing the predominant carbohydrate and serving as the primary energy reserve for the plant (Camire et al., 2009; Pfister & Zeeman, 2016; Li et al., 2021).

Potato starch is important from a technological perspective due to its functional properties, including thickening, gelling, coating, and encapsulation, which are largely determined by the structure and organisation of the two main polymers, amylose (AM) and amylopectin (AP). Differences in physicochemical, thermal, and pasting properties among potato starches also determine their suitability for various food and industrial applications (Li et al., 2006; Pfister & Zeeman, 2016; Sanchez-González et al., 2019). Breeding efforts have therefore focused on developing cultivars with improved processing characteristics, although clear differences between modern and heirloom cultivars in terms of AMC or starch granule morphology are not always observed. As industrial and food applications of potato starch continue to diversify, the characterization of starch parameters in breeding lines remains important for identifying valuable germplasm with properties suitable for specialised and emerging applications (Fajardo et al., 2013).

Current research has identified several factors influencing starch composition and quality in potato tubers, including genetic background, environmental conditions, tuber developmental stage, and agronomic practices. AMC is considered one of the most important parameters affecting the nutritional and technological properties of potato starch. Therefore, the aim of this review is to analyse the factors influencing starch composition and quality in potato tubers, with particular emphasis on changes in amylose content and the role of genetic, environmental, and agronomic factors in regulating these variations.

Materials and Methods

This review was conducted using a semi-systematic monographic approach to analyse scientific information on factors influencing starch composition and quality in potato tubers. The aim was to summarise research findings on the effects of genetic, environmental, and agronomic factors on potato starch

formation and properties. The literature search was performed using the EBSCO and CAB Abstracts databases, complemented by Google Scholar searches. The analysed literature included articles published in journals from major academic publishers, including Elsevier, Springer Nature, Wiley, Taylor & Francis, MDPI, and others.

This study used ChatGPT (GPT-5.3), a large language model developed by OpenAI, as a supportive tool for language editing and structuring ideas. The AI-generated suggestions were reviewed and critically evaluated by the author, and all final interpretations, analyses, and conclusions remain the responsibility of the author.

Results and Discussion

Structure and Composition of Potato Starch

Starch is the main component of potato tuber dry matter and the primary reserve carbohydrate of the plant. In potato tubers, starch generally accounts for approximately 66–80% of dry weight, although the exact amount may vary depending on cultivar and plant developmental stage (Li et al., 2006; van Eck, 2007; Pfister & Zeeman, 2016; Dupuis & Liu, 2019).

Chemically, starch is a polysaccharide composed of glucose units and occurs in two main forms: AM and AP. AM is mainly a linear polymer linked by α-1,4-glycosidic bonds, whereas AP has a highly branched structure containing both α-1,4- and α-1,6-glycosidic linkages (Hoover, 2001; Yusuph et al., 2003; Storey, 2007; Pfister & Zeeman, 2016; Dupuis & Liu, 2019; Wang et al., 2025). The relative proportion and molecular organisation of these polymers largely determine the physicochemical and functional properties of potato starch.

Starch granules contain crystalline and amorphous regions that influence their susceptibility to hydrolysis and other physicochemical changes. Limited hydrolysis mainly affects amorphous regions and may correlate with AMC, whereas more intensive hydrolysis also affects crystalline structures formed by AP (Yusuph et al., 2003).

The composition and structure of potato starch are also associated with its nutritional properties and digestibility. Lal et al. (2024) reported that the addition of potato peels to potato flesh may help moderate postprandial blood glucose responses by affecting starch digestibility parameters, including the glycaemic index and starch hydrolysis index. The incorporation of potato peels also increased total starch and AMC, likely due to the naturally occurring starch and carbohydrate fractions present in potato peel tissues.

Overall, the structure and composition of potato starch are primarily determined by the proportion and organisation of AM and AP, which influence nutritional, functional, and technological properties. These characteristics are further shaped by interactions among genetic, environmental, and agronomic factors.

Genetic Factors Influencing Potato Starch Composition

As summarised in Table 1, studies analysing the genetic diversity of potato starch have consistently demonstrated significant differences in starch composition, particularly in AM content, among potato genotypes.

Genetic background plays a key role in determining starch composition and physicochemical properties in potato tubers. AMC in potato starch typically ranges from approximately 17% to 25%, though considerable variation occurs among cultivars and genetic lines (Li et al., 2006).

Differences in starch composition are also associated with structural characteristics of starch granules. A negative correlation between AMC and starch granule diameter has been identified, indicating that smaller granules generally contain higher levels of AM. This relationship has been observed in both cultivated and wild potato species. Most commercial cultivars contain up to approximately 28% AM, whereas some wild potato clones may reach 30–33% AM (Jansen et al., 2001).

Increased AM levels may improve the nutritional properties of potato starch, as higher AMC is associated with greater resistance to enzymatic digestion and the formation of resistant starch (Camire et al., 2009). However, despite the importance of cultivar-related differences, studies conducted under uniform growing conditions suggest that physicochemical properties among potato cultivars may vary less than expected, indicating that starch functionality and digestibility are also influenced by additional interacting factors (Alvani et al., 2011).

Studies of coloured potato cultivars have demonstrated significant differences in AM content, phosphorus content, molecular structure, and pasting behaviour among genotypes, including yellow, purple, and red potatoes, which in turn affect rheological and functional properties relevant for food and industrial applications (Yang et al., 2018). Similarly, starch from light-coloured potato varieties has been reported to contain slightly higher AM levels than starch from coloured varieties (Krystyjan et al., 2022). Differences in starch molecular architecture have also been observed between mealy and waxy pigmented potatoes, where mealy starches show higher AMC, lower branching degree, a reduced proportion of short-chain AP fractions, and lower molecular weight (Wang et al., 2025). Higher AM concentrations may also be associated with structural differences in starch granules, including increased surface irregularities (Rivas et al., 2023).

Studies from different regions further support the strong influence of genetic factors. Research in Brazil reported relatively small variation in AMC among six potato varieties, although differences in AM and AP proportions affected starch granule structure and pasting properties (dos Santos et al., 2016).

In the United States, significant varietal effects on AMC were observed, with higher levels detected in certain cold-induced sweetening (CIS)-resistant cultivars (Jansky & Fajardo, 2014). Studies in India reported AM values ranging from approximately 15% to 23% among cultivars (Kaur et al., 2007), while research in Peru also confirmed significant varietal differences (Sanchez-González et al., 2019).

Overall, genetic factors strongly influence starch composition and properties in potato tubers; however, variation in the amylose–amylopectin ratio may also be influenced by environmental conditions and agronomic practices (Noda et al., 2004; Sanchez-González et al., 2019; Singh et al., 2018).

Environmental Factors Affecting Starch Composition

Environmental conditions during plant growth can significantly influence starch synthesis and accumulation in potato tubers. Studies summarised in Table 1 indicate that factors including location, altitude, temperature, and seasonal variability affect

starch composition, particularly AMC. Significant effects of genotype, environment, and genotype × environment interaction on AMC have been reported in potatoes grown under different environmental conditions (Ahmed et al., 2019; Hu et al., 2023; Jansky & Fajardo, 2014). In addition, temperature conditions during the growing season may influence starch composition, as higher average temperatures were associated with increased AMC in potato starch (Brążkiewicz et al., 2025).

Several studies demonstrated that potatoes cultivated at higher altitudes tend to exhibit increased AM levels and altered amylose–amylopectin ratios compared with potatoes grown at lower elevations (Hu et al., 2023; Šimková et al., 2013). Environmental variation related to altitude has also been shown to affect physicochemical and functional starch properties, including swelling power, solubility, absorption capacity, and pasting behaviour (Rohima et al., 2024, 2025).

Seasonal and climatic conditions may further contribute to variation in starch composition. Research conducted in the United States revealed that location and year significantly affect AMC, suggesting that climatic variability influences starch biosynthesis in potato tubers (Jansky & Fajardo, 2014). However, not all studies observed a consistent environmental effect, as research in the Czech Republic reported no statistically significant influence of year on AMC (Šimková et al., 2013).

Overall, available studies indicate that environmental conditions can influence potato starch composition and functionality, although the magnitude of these effects depends on genotype and growing conditions.

Changes in Amylose Content During Maturation

The developmental stage of potato tubers influences starch accumulation and composition. Cultivar maturity type and growing season length significantly affect tuber yield and starch production. Early-maturing cultivars generally have a shorter vegetation period and therefore tend to accumulate lower starch content and produce smaller tuber yields than late-maturing cultivars, which usually achieve greater starch accumulation during extended growth periods (van Eck, 2007; Camire et al., 2009).

Studies investigating the relationship between tuber maturity and AMC have produced variable results. Research conducted in the Czech Republic on sixteen potato cultivars identified the lowest AMC in a very late cultivar and the highest in a semi-early cultivar, although the effect of growing season length was not consistently expressed across all genotypes (Šimková et al., 2013).

Additional insight into changes in AMC during tuber development was provided by field experiments in the United States. A three-year study involving eleven cultivars demonstrated that AMC was highest during early tuber formation and gradually decreased as tubers matured, declining from approximately 30.0% in late June to 26.8% in late August (Jansky & Fajardo, 2016). However, not all studies have identified a clear relationship between maturity and AMC. Research conducted in Denmark reported that AMC in four potato cultivars was independent of harvest date and tuber size (Christensen & Madsen, 1996).

Changes in starch molecular structure during tuber development may additionally influence starch functionality. Variations in AP chain-length distribution during starch granule development have been associated with changes in pasting behaviour, gelatinisation, retrogradation, and digestibility (Yang et al., 2021).

Overall, available studies indicate that tuber maturation and growing season duration may influence starch accumulation and AMC, although the extent and direction of these changes depend on cultivar characteristics and environmental conditions.

Agronomic Practices Influencing Potato Starch Composition

As summarised in Table 1, agronomic management practices may influence starch composition and functional properties in potato tubers. Among agronomic factors, nitrogen fertilisation is considered one of the most important practices in potato production. However, studies conducted in Brazil showed that nitrogen fertilisation did not significantly affect AMC in potato starch (Ebúrneo et al., 2018). In contrast, research on sweet potato demonstrated that increasing nitrogen levels reduced AMC and increased the proportion of AP (Duan et al., 2019), suggesting that nitrogen effects on starch composition may vary among crop species.

Agronomic treatments may also affect starch characteristics. Research conducted in Poland demonstrated that combined agronomic treatments increased AMC in potato starch (Brążkiewicz et al., 2025).

Overall, agronomic practices can influence starch composition and quality in potato tubers, although their effects are often smaller than genetic influences.

Postharvest Storage Effects on Potato Starch Quality

Whereas long-term storage reduced AM levels by approximately 0.9 percentage points, starch quality was only slightly affected when constant storage conditions and appropriate potato seed treatment products were applied, suggesting that suitable storage management may help maintain starch quality during prolonged storage (Brążkiewicz et al., 2025). Similarly, studies evaluating potato cultivars under different production environments indicated that storage and production conditions generally had a smaller influence on AM levels than cultivar-related differences (Fajardo et al., 2013).

Storage-related changes may also affect starch retrogradation behaviour. Studies have shown that AM retrogradation occurs mainly during the early stages of storage, whereas AP retrogradation becomes more pronounced during long-term storage. Changes in viscoelastic properties, hardness, resistant starch content, and gel stability during refrigerated storage

have also been associated with AMC and AM chain length (Dobosz et al., 2019).

Post-harvest storage conditions can further modify starch composition and physicochemical properties. Storage treatments may influence AMC depending on cultivar and storage regime (Jansky & Fajardo, 2014), while prolonged storage can reduce AM levels (Poberežny et al., 2021). Low-temperature storage has been associated with smaller starch granules, reduced solubility, and changes in thermal, pasting, and textural properties, whereas AMC and swelling power are generally less affected (Singh et al., 2008; Kaur et al., 2009).

Overall, storage conditions can influence starch composition and quality in potato tubers, although their effects are generally smaller than those associated with genetic factors.

Conclusions

1. Potato starch composition is mainly determined by the proportion and structure of amylose and amylopectin, which influence its functional, nutritional, and technological properties.
2. Genetic factors are the primary source of variability in starch composition, with significant differences in amylose content and physicochemical properties observed among potato cultivars, particularly in wild and coloured genotypes.
3. Environmental conditions (e.g., temperature, altitude, and location) influence starch synthesis and composition, but their effects are strongly dependent on genotype and show inconsistent patterns across studies.
4. Tuber developmental stage and post-harvest storage can modify amylose content and starch functionality; however, the magnitude and direction of these changes vary, indicating incomplete understanding of underlying mechanisms.
5. Recent research increasingly focuses on starch fine structure, genotype × environment interactions, and post-harvest modifications, while remaining gaps exist in explaining variability across studies and standardising methodological approaches.

Abstract
Fungi from the genera *Alternaria* and *Stemphylium* belong to the family *Pleosporaceae* and are responsible for severe agricultural yield losses in temperate zones affecting various hosts, including tomatoes *Solanum lycopersicum* L. Both *Alternaria* spp. and *Stemphylium* spp. are characterized by similar disease symptoms, thus challenging the management of tomato diseases caused by these fungi. In our study, a total of 17 greenhouses and high tunnels were surveyed in the Baltic region from 2022 to 2024 for the collection of tomato samples with typical disease symptoms. Fungi were recovered from symptomatic tomato leaves and fruits on potato dextrose agar (PDA) media and characterized based on colony morphology. Further identification of fungal strains at the genus and subgeneric section levels was based on the analysis of the ITS region. A total of 845 leaves and fruits representing brown to black necrotic lesions were collected and 1181 fungal strains were obtained, predominantly small-spored *Alternaria* spp. (n=575) representing three subgeneric sections (*Alternaria*, *Ulocladiodes,* and *Infectoriae*). Large-spored *Alternaria* species comprised within *Alternaria* section *Porri* (n=125), *Stemphylium* spp. (n=60) and other fungi (n=421) were also isolated from tomatoes. Brown spot disease of tomatoes associated with small-spored *Alternaria* spp. dominated in 2023 and 2024 with the occurrence of 71-80% in the Baltic region. The occurrence of tomato diseases caused by large-spored *Alternaria* spp. was 20-60% whereas those caused by *Stemphylium* spp. had the occurrence of 29-60%, depending on the sampling location and year.
Keywords: *Solanum lycopersicum* L., fungal diseases.

Introduction

Tomatoes *Solanum lycopersicum* L. are characterized by various health benefits due to high levels of biologically active compounds, predominantly carotenoids and phenols (Bertin et al., 2025; Gómez-Romero et al., 2010; Perveen et al., 2015). Fungal diseases are associated with reduced yield and quality of tomatoes in temperate regions (Ally et al., 2023; Schmey et al., 2024; Wang et al., 2025).

Considerable yield losses in tomato production are caused by two related genera within phylum Ascomycota, class Dothideomycetes, family Pleosporaceae, order Pleosporales, viz., *Alternaria* (Bessadat et al., 2017; Kokaeva et al., 2022; Schmey et al., 2024; Thomma, 2003) and *Stemphylium* (Bessadat et al., 2022; Franco et al., 2017; González-Ghiena et al., 2025; Torres et al., 2024).

Both *Alternaria* spp. and *Stemphylium* spp. are characterized by production of various secondary metabolites, including mycotoxins and phytotoxins (Bhunjun et al., 2024; Kim & Dettman 2025; Stricker et al., 2021). Therefore, these fungi are also associated with human health threats (Grignano et al., 2025; Zhao et al., 2025) and food safety (Manno et al., 2025; Tournas et al., 2005).

To date, over 400 fungal species are comprised in the genus *Alternaria* that is divided into 30 subgeneric sections (Ahmadpour et al., 2025; Li et al., 2023). Furthermore, a total of 37 species are described in the genus *Stemphylium* (Ahmadpour et al., 2024; Brahmanage et al., 2019, 2020; Crous et al., 2020; Marin-Felix et al., 2019; Phukhamsakda et al., 2020; Qian et al., 2023; Woudenberg et al., 2017). Fungi from both genera are characterized by similar colony morphology and micro-morphological characteristics, for instance, production of multiseptated and pigmented conidia that are indistinguishable at early stages of development (Simmons, 2007; Woudenberg et al., 2013, 2014, 2017).

Previous studies have confirmed that morphological characteristics do not allow reliable identification of *Alternaria* spp. and *Stemphylium* spp.; therefore, molecular phylogenetic analysis is required for their delimitation (Bessadat et al., 2022; Dettman & Eggertson, 2022; Lawrence et al., 2016; Li et al., 2022; Woudenberg et al., 2013, 2017).

The precise identification of tomato diseases caused by *Alternaria* spp. and *Stemphylium* spp. is necessary for the development of effective control strategies. There are limited reports available on fungi from the genera *Alternaria* and *Stemphylium* affecting the production of greenhouse tomatoes in the Baltic region (Dučkena & Bimšteine, 2023; Dučkena et al., 2024, 2026; Shidlauskiene & Surviliene, 2002) and also globally (Ally et al., 2023; Sanoubar & Barbanti, 2017).

The aim of the present study was to characterize morphological characteristics of *Alternaria* spp. and *Stemphylium* spp. and analyze the occurrence of tomato diseases caused by these fungi in the Baltic region.

Materials and Methods

The research was conducted from 2022 to 2024 and comprised a total of 17 greenhouses and high tunnels, including 13 integrated and 4 organic farming systems of tomato cultivation in the Baltic region. These

included the following locations: i) Bērze, Daugmale, Līvbērze, Iecava, Jaunsvirlauka, and Vircava from Latvia; ii) Jõgeva, Vedu, Koimula, and Lemmatsi from Estonia; and iii) Babtai, Ringaudai, Virbaliskiai, and Karkiskes from Lithuania.

Tomato diseases caused by *Alternaria* spp. and *Stemphylium* spp. were identified based on visual evaluation of symptoms and confirmed via light microscopy. Symptomatic samples were collected at the beginning and end of intensive tomato production and brought to the Plant Pathology Scientific Laboratory (LBTU, Latvia). Tomatoes were examined for conidia of *Alternaria* spp. and *Stemphylium* spp. using an Olympus BX43 microscope (Olympus Cooperation, Japan). The obtained data were compared with criteria from Simmons (2001, 2007).

Plant tissue samples (0.5 cm^2) were excised from symptomatic tomatoes and 1% solution of sodium hypochlorite (NaOCl) was used for their sterilization for 1 min, followed by rinsing three times in distilled water. Thereafter, plant samples were transferred to Petri dishes containing potato dextrose agar media (PDA) amended with penicillin (0.1 mg L^{-1}) and streptomycin (0.1 mg L^{-1}). After seven days of incubation in darkness at 23 °C, a single representative colony from each PDA plate was selected for purification according to Leyronas et al. (2012).

Further analyses of *Alternaria* spp. and *Stemphylium* spp. strains were conducted at the Institute of Research on Horticulture and Seeds, France. The microwave mini-prep method (Goodwin & Lee, 1993) was used for the extraction of the genomic DNA. The polymerase chain reaction (PCR) analyses of the internal transcribed spacer regions 1 and 2 (ITS1, ITS2) and intervening 5.8S nuclear ribosomal DNA (nrDNA) were conducted according to White et al. (1990). Sanger sequencing of the obtained amplicons was conducted by Eurofins Genomics (Ebersberg, Germany). Further identification of fungal strains at the genus and the subgeneric section levels was conducted according to Woudenberg et al. (2013, 2014, 2015, 2017).

The occurrence of tomato diseases caused by fungi from the genera *Alternaria* and *Stemphylium* was calculated using the number of greenhouses where the disease was observed compared to the total number of greenhouses surveyed in each country, expressed as a percentage.

Results and Discussion

Fungal isolation and identification

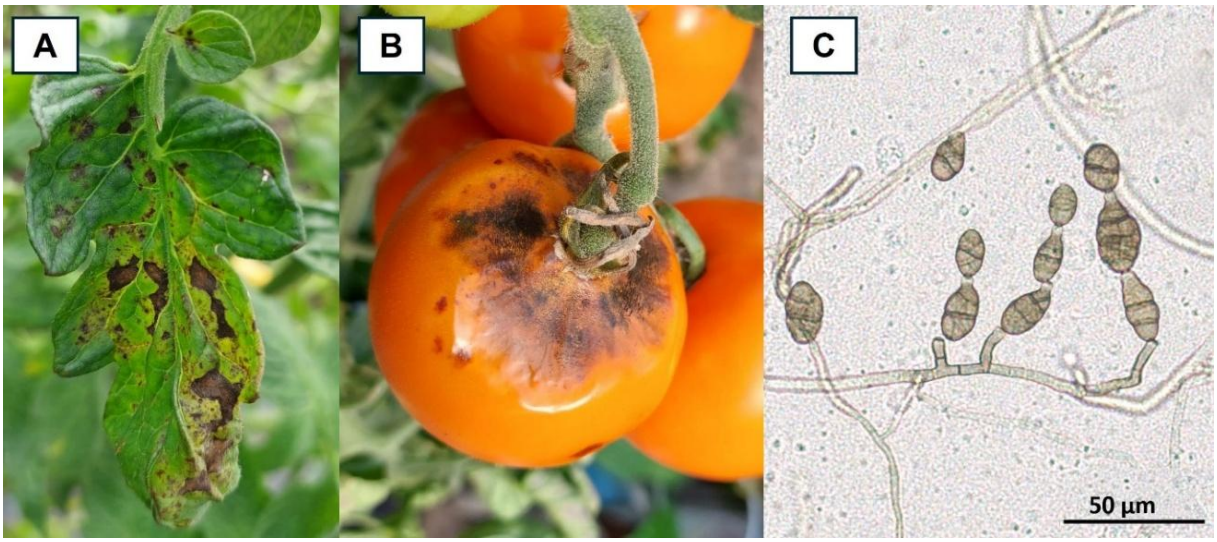
A total of 845 tomato leaves and fruits with disease symptoms caused by *Alternaria* spp. and *Stemphylium* spp. were obtained and 1181 fungal strains were isolated from symptomatic samples. A total of 4 groups were identified using the analysis of colony morphology, the size and catenation of conidia. First, small-spored *Alternaria* spp. formed small conidia (length <60 µm) in chains (n=575). Second, large-spored *Alternaria* spp. (n=125) were characterized by the formation of large conidia (length >60 µm). Third, *Stemphylium* spp. (n=60) formed conidia ≤55 µm in length. Fourth, other fungi isolated from tomatoes were excluded from further analysis (n=421).

A total of 300 representative strains of *Alternaria* spp. and *Stemphylium* spp. were selected for further identification using the ITS region. The National Center for Biotechnology Information (NCBI, USA) BLAST analysis of the ITS region confirmed the occurrence of *Stemphylium* spp. along with *Alternaria* spp. from four sections. These included the sections *Porri* (32%), *Infectoriae* (24%), and *Alternaria* (22%) identified in Latvia, Lithuania, and Estonia. Members of the section *Ulocladioides* (1%) were identified in Jõgeva (Estonia) and Ringaudai (Lithuania). Our results align with reports by Schmey et al. (2024) confirming sections *Alternaria*, *Porri*, *Infectoriae*, and *Ulocladioides* as disease causal agents in tomatoes.

However, other studies have reported on greater diversity of *Alternaria* spp. associated with tomatoes, for instance, members of the sections *Japonicae* (Bessadat et al., 2020), *Brassicicola*, *Dianthicola* (Woudenberg et al., 2013), *Embellisia* (Sadeghi & Mirzaei, 2018) along with *Embellisioides* and *Eureka* (Bessadat et al., 2021).

Characterization of tomato diseases associated with small-spored Alternaria species

In the present study, small-spored *Alternaria* spp. represented three sections (*Alternaria*, *Ulocladiodes*, and *Infectoriae*) were obtained from symptomatic leaves and fruits of tomatoes (Figure 1) in line with previous studies (Bessadat et al., 2017; Gherbawy et al., 2018; Kokaeva et al., 2018). In the Baltic region, these fungi were associated with small, brown to black lesions without concentric rings on symptomatic leaves as reported by Schmey et al. (2024).



Brown spot disease of tomatoes caused by small-spored *Alternaria* spp. dominated in the Baltic region in 2023 and 2024. In Estonia, this fungal disease was noted in 4 of the 5 surveyed greenhouses located in Jõgeva, Vedu, and Koimula (occurrence 80%). In Latvia, brown spot disease of tomatoes was identified in 5 of the 7 surveyed greenhouses located in Bērze, Daugmale, Līvbērze, and Iecava (occurrence 71%). In Lithuania, this fungal disease was recorded in 4 of the 5 surveyed greenhouses located in Babtai, Ringaudai, Virbaliskiai, and Karkiskes (occurrence 80%).

Early blight (EB) disease caused by large-spored *Alternaria* species (section *Porri*) was detected every year during intensive tomato production (from August to September).

Characterization of tomato diseases caused by large-spored Alternaria species

Early blight (EB) was identified on tomato leaves characterized by brown, necrotic lesions with yellow halos. Compared with small-spored *Alternaria* spp., those of large-spored *Alternaria* spp. were distinguished by larger lesions with typical concentric rings (Figure 2) in line with reports from other studies (Bessadat et al., 2017; El Gobashy et al., 2018; Ding et al., 2019; Zhao et al., 2022).

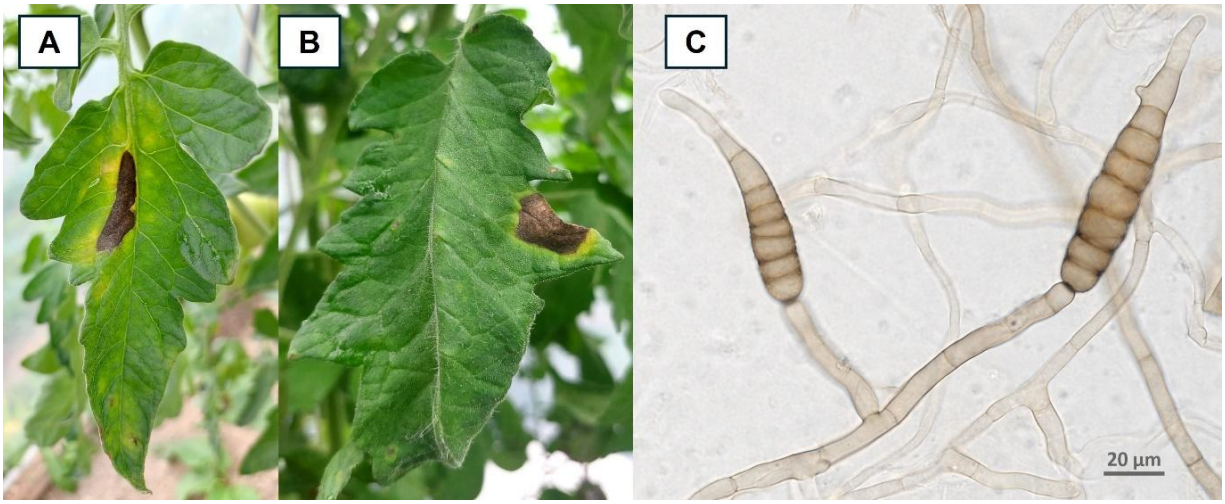


Figure 1
Symptoms of brown spot disease of tomatoes in the Baltic region caused by small-spored Alternaria spp.: dark brown lesions on leaves (A), black, sunken lesions on fruits (B), and chains of conidia of small-spored Alternaria spp. at 200× magnification (C). Scale bar = 50 µm. Photos A and B by L. Dučkena

The occurrence of early blight in Estonia during the survey was 60%, and it was identified in Vedu and Jõgeva in 2023 and 2024. In contrast, the occurrence of early blight in Latvia was 29%, and it was recorded in Bērze and Iecava (2023), followed by Bērze and Daugmale (2024). Moreover, the occurrence of early blight in Lithuania was 20%, and it was recorded in Ringaudai during 2023 and 2024.

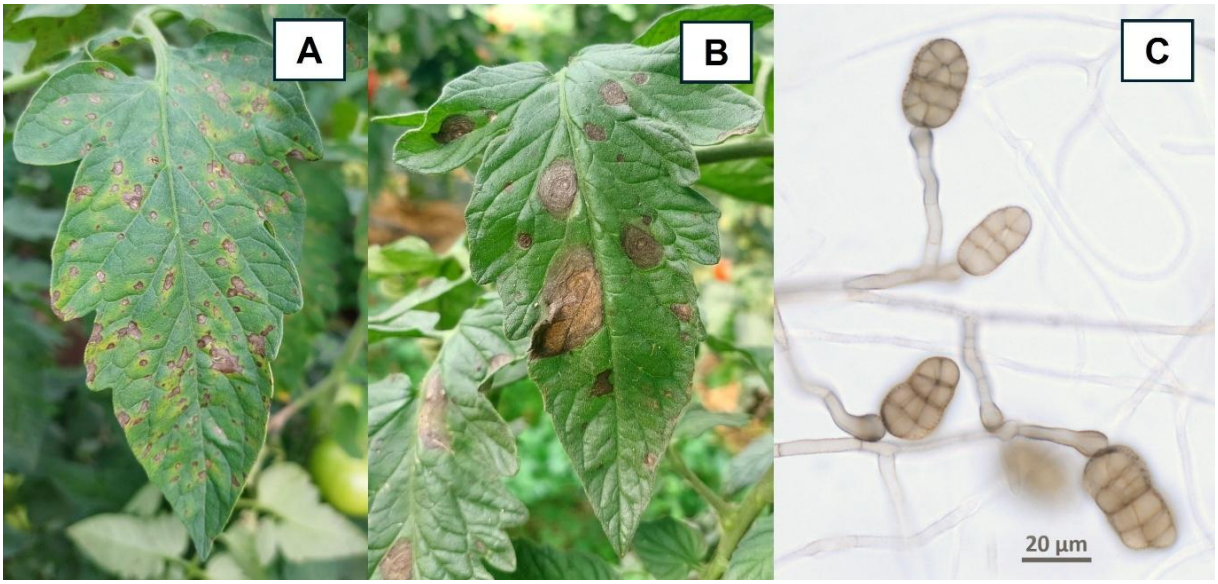
Moreover, a complex infection caused by both large-spored and small-spored *Alternaria* species was observed on symptomatic leaves at the end of intensive tomato production in Latvia, Lithuania, and Estonia.

Figure 2
Symptoms of early blight of tomatoes in the Baltic region caused by large-spored Alternaria species comprised within the section Porri: elongated (A) or circular (B) dark brown lesions with typical concentric rings that are surrounded by yellow halos, and conidia of large-spored Alternaria spp. at 400× magnification (C). Scale bar = 20 µm. Photos A and B by L. Dučkena

Previous studies have also confirmed the co-occurrence of large-spored *Alternaria* species (section *Porri*) with small-spored *Alternaria* spp. (sections *Infectoriae* and *Alternaria*) on symptomatic tomatoes and potatoes in different regions of Russia (Kokaeva et al., 2018). Therefore, it is also named as early blight/brown spot disease complex affecting various solanaceous hosts (Vandecasteele et al., 2018).

Tomato diseases caused by fungi from the genus Stemphylium

In the present study, *Stemphylium* spp. were associated with symptomatic leaves of tomatoes in line with previous reports confirming these fungi as important foliar pathogens of tomatoes (Bessadat et al., 2022; González-Ghiena et al., 2025; Torres et al., 2024). *Stemphylium* spp. are also associated with leaf spots on



other related hosts from the *Solanaceae* family, for example, potatoes (Yang et al., 2018), pepinos *Solanum muricatum* Aiton (Nasehi et al., 2016), peppers *Capsicum annuum* L. (Sun & Huang, 2022), and wild eggplants *Solanum torvum* Sw. (Xie et al., 2016). Moreover, *Stemphylium* spp. are also infecting tomato fruits causing brown specks but are not affecting tomato stems or petioles (Bessadat et al., 2022). Tomato diseases caused by fungi from the genus *Stemphylium* are most frequently referred to as a grey leaf spot of tomatoes (Franco et al., 2017; Nasehi et al., 2012; Sun et al., 2016).

In the Baltic region, *Stemphylium* spp. were isolated mainly from brown lesions on tomato leaves (Figure 3A). Similar observations have been reported in Algeria by Bessadat et al. (2022), confirming that *Stemphylium* spp. are associated with small, dark brown spots leading to leaf chlorosis, necrosis, and defoliation of tomatoes. Reports from Germany also suggested that small, brown to dark necrotic lesions are associated with *Stemphylium* spp., referring to this disease as brown spot of tomato (Karbowy-Thongbai et al., 2023). Moreover, reports from Taiwan have suggested that tomato diseases caused by these fungal pathogens should be referred to as Stemphylium leaf spot of tomato (Huang & Tsai, 2017).

Disease symptoms caused by *Stemphylium* spp. were observed every year during intensive tomato production (from August to September). In Lithuania, fungal diseases caused by *Stemphylium* spp. were observed in Karkiskes and Babtai, with the occurrence of 40% in 2023 and 60% in 2024. In Latvia, tomato diseases caused by fungi from the genus *Stemphylium* were noted in Bērze and Iecava and their occurrence during 2023 and 2024 was 29%. In Estonia, the occurrence of fungal diseases caused by *Stemphylium* spp. was 40% in 2023, and it was observed in Koimula and Jõgeva, whereas in 2024 the occurrence was 60%, and it was recorded in Vedu, Jõgeva, and Lemmatsi.

Figure 3

Symptoms of brown leaf spot of tomatoes caused by fungi from the genus Stemphylium in the Baltic region: small brown spots with or without yellow halos (A); necrotic lesions with concentric rings representing co-occurrence of Alternaria spp./ Stemphylium spp. (B); and conidia of Stemphylium spp. at 400× magnification (C). Scale bar = 20 µm. Photos A and B by L. Dučkena

Co-occurrence of fungi from the genera Alternaria and Stemphylium

In the current study, both large-spored and small-spored *Alternaria* spp. were characterized by co-occurrence with *Stemphylium* spp. on tomatoes (Figure 3B). Moreover, the complex infection caused by fungi from the genera *Alternaria* and *Stemphylium* was mainly observed at the end of intensive tomato production, i.e., from mid-September to the end of September. The co-occurrence of these fungi was characterized by a mixture of symptoms that are indistinguishable using visual observations alone in line with reports from Bessadat et al. (2022).

Previous studies have confirmed that *Alternaria* spp./*Stemphylium* spp. complex is associated with necrosis and defoliation of tomato plants (Bessadat et al., 2022) along with black, sunken lesions on fruits (Feng et al., 2025). The co-occurrence of *Alternaria* spp. and *Stemphylium* spp. has been recorded in various tomato growing areas, including Australia (Feng et al., 2025), Algeria (Bessadat et al., 2017, 2022), and China (Zhao et al., 2022).

Interestingly, complex infections involving both *Alternaria* spp. and *Stemphylium* spp. have also been reported on other hosts, such as onion *Allium cepa* L. (Abdel-Rahim et al., 2017; Reyes-Tena et al., 2024),

leek *A. ampeloprasum* L. (Suheri & Price, 2001), lettuce *Lactuca sativa* L. (Bessadat et al., 2025), and faba bean *Vicia faba* L. (Bankina et al., 2021).

Conclusions

1. The current study confirms a wide range of fungal pathogens comprised within four subgeneric sections of the genus *Alternaria* and *Stemphylium* spp. as disease causal agents of tomatoes that may vary in their interaction with the host plant, sensitivity to fungicides, and aggressiveness.
2. The co-occurrence of both large-spored and small-spored *Alternaria* spp. with *Stemphylium* spp. on symptomatic tomatoes in the Baltic region highlights the complexity of management of tomato diseases.
3. In further studies, multi-locus phylogenetic analyses are necessary for species identification and subsequent development of tomato disease control strategies.

Abstract
The Western honeybee (*Apis mellifera*) is an important agricultural pollinator. The ability of honeybee colonies to survive the winter is significantly affected by rapid temperature fluctuations. These sharp changes prevent honeybees from maintaining the essential hive temperature, resulting in high mortality. The thermal conductivity and durability of hive materials are among the factors influencing overwintering success. To assess how hive thermal conductivity affects overwintering, this study evaluated whether shielding hive walls with a thermoreflective surface could maintain stable internal conditions and improve overwintering survival rates. Four control and four shielded hives were continuously monitored (weight, ambient and internal hives temperatures, internal hives CO_2 and RH levels) between 24 September 2024 and 5 March 2025, covering cluster formation and overwintering periods. In autumn, anomalously warm weather triggered wasp attacks on all hives, but sustained attacks only destroyed one control hive. Despite losing one shielded hive to nosemosis in early winter, three shielded colonies successfully overwintered. Conversely, two additional control hives collapsed over winter, leaving only a single weak surviving colony. Data from the sensors confirmed that shielding helped maintain a higher internal temperature during autumn and winter, enabling honeybees to actively defend against wasp attacks and achieve greater overwintering success. These results suggest that shielding hives with a thermoreflective surface can be an effective method for reducing honeybee winter mortality.
Keywords: Carniolan honeybee, aluminium foil, beekeeping, microclimate.

Introduction

The Western honeybee (*Apis mellifera*) is considered an important pollinator due to its efficiency and widespread availability. Bee-assisted pollination influences the productivity and profitability of many crop varieties (Khalifa et al., 2021). In a study of 87 of the world's most utilised food crops, which together account for 35% of total crop production, it was concluded that their ability to produce fruit and seeds depends directly on pollination (Klein et al., 2007). Consequently, a decline in pollinator numbers may negatively impact global agriculture and food trade (Gallai et al., 2009).

Assessing honeybee colony mortality across 5,798 apiaries in 17 European countries revealed that winter colony losses range from 2% to 32% (Jacques et al., 2017). In another study spanning 37 countries worldwide, winter colony losses varied from 7.4% to 36.5%, with average rates reaching 18.1% (Gray et al., 2023).

Individual mortality and colony losses are influenced by various factors and can be categorised into manageable, semi-manageable, and unmanageable. Key manageable factors include beekeeping practices and the use of agricultural pesticides. Among semi-manageable biotic factors are pests and pathogens, such as the varroa mite *Varroa destructor* and the fungus *Nosema ceranae*, whose negative impact on honeybee population density is gradual. Conversely, unmanageable factors include variable climate conditions, which have a starkly negative impact on honeybee colonies (Gregorc, 2020; Hristov et al., 2020; Van Esch et al., 2020). The ability of honeybee colonies to survive the winter is significantly affected by rapid temperature changes (Insolia et al., 2022; Switanek et al., 2017).

Honeybee colonies regulate the air temperature within the hive, cooling it in summer and maintaining warmth inside the honeybee cluster in winter. When the outside temperature falls below 10 °C, honeybees start to form a winter cluster (Meikle et al., 2022; Stabentheiner et al., 2021). However, during sharp ambient temperature fluctuations in winter, honeybees may not be able to adapt quickly and maintain the temperature required for colony survival, thus leading to a rapid loss of a large number of honeybees (Jarimi et al., 2020).

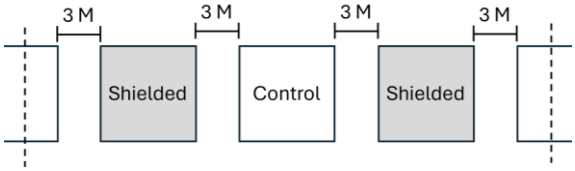
Thermoreflective surfaces are widely used in industrial refrigeration equipment, frozen food transport packaging and construction, where maintaining stable internal temperatures is required regardless of ambient conditions. Given the ability of thermoreflective surfaces to slow down temperature changes or maintain a constant internal temperature, the idea arose to apply thermoreflective surface technology to the inner walls of the hives. It was hypothesised that utilising passive heat reflection could help honeybees better maintain hive temperature despite ambient temperature fluctuations. Thus, by reducing the impact of ambient air temperature fluctuations on honeybee colonies, this strategy would decrease winter honeybee mortality.

Beyond thermoregulation, relative humidity (RH) and internal carbon dioxide (CO_2) levels are important indicators of a honeybee colony's overall health. The optimal RH range for a colony is 50-70% (Amdam & Omholt, 2002; Hou et al., 2016). During the cluster formation period and throughout the winter, honeybees regulate moisture exclusively within the cluster itself. Both extremes in humidity represent risks. Thus, excessively low humidity causes desiccation of the cluster's inner layers, increasing honeybee mortality. Conversely, insufficient ventilation leads to condensation

on the hive walls and within the cluster, creating a cold and damp environment. This increases honeybees' energy demands and facilitates the proliferation of mould and bacteria in unoccupied hive spaces. Consequently, colony health may be compromised, leading to diminished colony size at the onset of spring (Kutby et al., 2024).

Similarly, CO_2 concentrations reflect metabolic activity and the efficacy of ventilation. Maintaining appropriate CO_2 levels is essential for preserving colony health. While CO_2 in well-ventilated areas approximates the ambient atmospheric concentration of 0.04-0.05% (400-500 ppm), intra-hive levels exhibit both diurnal and seasonal variations driven by air exchange rates, population size, and ambient temperatures (Newton et al., 2022). In more enclosed areas of the hive, CO_2 typically exceeds 5,000 ppm (Newton et al., 2024). However, prolonged exposure to substantially high CO_2 levels subjects bees to hypercapnia and hypoxia, which may impair immunity, cause spatial disorientation, and potentially increase mortality rates (Human et al., 2013). Under chronically unfavourable microclimatic conditions, the combined stress and energetic costs of intensified ventilation divert resources away from immune maintenance, leaving the colony highly susceptible to disease (Kovac et al., 2007; Stabentheiner et al., 2010). Because intense ventilation can cool the hive, colonies must carefully balance air exchange with heat conservation (Bujok et al., 2002), intentionally tolerating higher CO_2 levels in the centre of the winter cluster.

Using the above-mentioned sensor-transmitted temperature, RH, and CO_2 level recordings, the aim of this study was to investigate the impact of hive wall shielding with a thermoreflective material on the behaviour of honeybee colonies during cluster formation and overwintering.

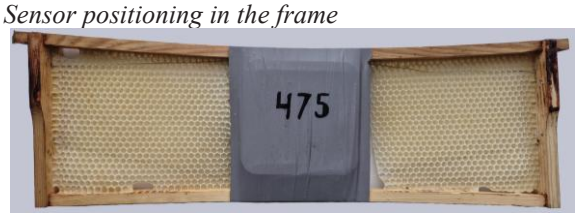


Materials and Methods

Eight Carniolan honeybee colonies *(Apis mellifera carnica)*, each comprising a queen and approximately 3,000 workers, were sourced from Ogre district, Latvia (56°54'21.6''N 24°25'56.3''E). Experiments were conducted in Dreilini, Ropazi municipality, Latvia (56°55'54.2''N 24°15'00.0''E) from 24 September 2024 to 5 March 2025, with weekly visits to assess hive condition and colony behaviour. Eight ten-frame Farrar-style expanded polystyrene (EPS) hives (BeeBox Dadant, Paradise Honey; 170 x 450 x 500 mm, 1.5 kg) were arranged in a single row at 3 m intervals, alternating between control and shielded groups (Figure 1).

To protect hives against environmental factors, the control group was coated with white Bostik Super Colour Epoxy (Bostik, USA), while the shielded group was coated with silver Bostik Super Colour Metallic (Bostik, USA) containing aluminium powder. The hives were left in the open air for seven days to allow the paint to dry. Internal surfaces of the shielded hives (excluding the bottom mesh) were lined with 0.03 mm self-adhesive aluminium tape (Alnor TAPE AL, Poland).

Figure 1



Arrangement of hives during the experiment

Hives were continuously monitored by recording weight, ambient and internal temperatures, internal CO_2 and RH levels. Mass and ambient temperature were recorded hourly via BeeSage (Latvia) smart scales, while an internal sensor (Connected AirWits, Connected Inventions, Finland) monitored CO_2, temperature, and humidity every 30 minutes. All data were transmitted to a cloud server. The sensors were taped to the centre of the comb frame and placed in the centre of the hive (Figure 2).

Figure 2

Sensor positioning in the frame

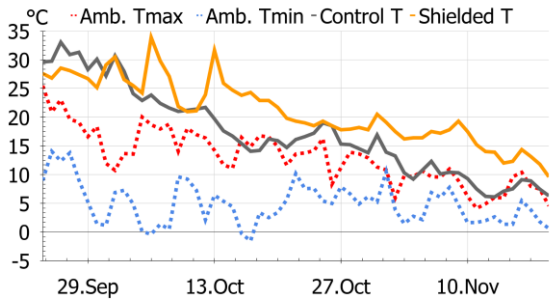
At the onset of winter, honeybees typically position themselves in the lower or middle part of the hive on empty wax combs, located directly below the line of capped honey. During the winter, as they consume food, the cluster slowly moves vertically upwards and sometimes towards the back. In cold weather, bees rarely move horizontally (from one frame to the next), as crossing the space outside the warming cluster carries the risk of freezing (Mitchell, 2023). To determine the statistically average temperature of the colonies within a single group, the median (central tendency) temperature of each group was measured on an hourly basis. If one of the colonies moved too far from the sensor, its results would minimally affect the group's average temperature.

All recorded data were compiled in LibreOffice 25.2.2 and analysed using RStudio 1.4. Hive internal parameters were expressed as medians, while ambient temperature was characterised by the daily highest (T_{max}) and lowest (T_{min}) temperatures. Group means were compared using one-way ANOVA with standard deviations (SD) only for the cluster formation period. Statistical analysis was not performed for the overwintering period, as only one colony in the control group survived. To evaluate relationships between colony and environmental conditions, Pearson correlation coefficients (r) were calculated for mean

temperature, RH, and CO_2 against ambient T_{max} and T_{min}. This approach was justified by the linear relationship between variables and the normal distribution (Caldwell & Cheuvront, 2019).

Results and Discussion

Observations were categorised into two distinct periods: cluster formation period and overwintering.



The cluster formation period began on 24 September 2024, following the removal of the honey store and the restriction of the hive. Triggered by T_{max} below 10 °C, honeybees initiated winter cluster formation. The process concluded on 19 November once the hives mean internal temperature reached approximately 10 °C.

In autumn 2024 in Latvia, the seasonal average temperature of 9.6 °C was the third warmest on record, exceeding the climatic norm by 2.5 °C. September was the warmest on record at 16.1 °C (3.8 °C above the norm), with temperatures above the daily average for nearly the entire month. This warming trend persisted through October and November, with temperatures remaining 1.6 °C and 2.0 °C above their respective monthly norms (LVGMC, 2024). The duration of the cluster formation period was extended due to inconsistent daytime temperatures, as periodic warming inhibited the formation of a stable winter cluster. If ambient temperature in the cluster formation period exceeds 10 °C, the cluster becomes diffuse, and honeybee activity increases (Rajagopalan et al., 2024; Stabentheiner et al., 2003).

The mean T_{max} in the apiary was 13.78 ± 4.68 °C, while the T_{min} in this period reached 4.96 ± 3.82 °C (Figure 3). The mean temperatures differed significantly between experimental groups (p = 0.00045). The shielded group maintained a higher temperature (20.93 ± 5.58 °C) compared to the control group (16.61 ± 7.48 °C; p = 0.00045).

Figure 3

T_{max} and T_{min} of the apiary, and T_{mean} of the control and shielded groups (°C) in the cluster formation period

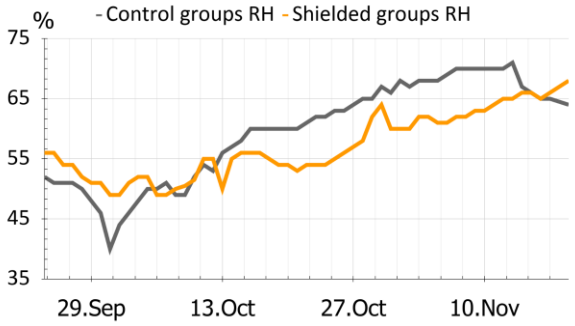
The SD of mean hive temperatures reveals higher fluctuations in the control group than in the shielded group. The ability of honeybees to actively regulate the temperature within the cluster means that temperature fluctuations in the hive, particularly near the cluster, should be smaller than ambient temperature fluctuations. Therefore, a smaller SD in the shielded group suggests better thermoregulation.

Internal and ambient temperatures were strongly, positively correlated in both groups ($p < 0.0001$). For the control group, this correlation held against both T_{max} (r = 0.917, $p < 0.0001$) and T_{min} (r = 0.753, $p < 0.0001$), indicating high susceptibility to ambient temperature fluctuations. This exposure placed a greater load on the honeybee cluster during cold nights, possibly causing oxidative stress, which may impair their immunocompetence and accelerate physiological ageing (Frunze et al., 2024; Kunat-Budzyńska et al., 2025).

Conversely, the shielded group better retained cluster-generated heat and resisted cooling during the coldest periods. This difference is likely due to the foil reflecting thermal radiation generated by the cluster, thus reducing energy loss. However, the strong correlation with T_{min} suggests that the foil's high thermal conductivity did not prevent heat loss on the coldest nights. This implies that foil shielding may be a useful addition but not a replacement for traditional hive insulation aimed at reducing thermal conductivity.

Higher average daily temperatures induced phenological shifts, leading to intensive wasp attacks observed on 13 November 2024. Certain wasp species, most notably *Vespula vulgaris* and *Vespula germanica*, are aggressive predators of honeybee colonies. In autumn, as natural forage becomes scarce, wasps may intensify their search for additional food sources, including honey and bees. While they rarely cause large-scale colony losses, weakened colonies or hives with reduced populations are particularly vulnerable during this period of heightened foraging activity (Beggs et al., 2011).

On average, wasps visited each hive 10 times per minute, primarily attacking honeybees to harvest thoracic muscle tissue for protein. Control hives experienced significantly higher wasp attacks. It is hypothesised that the higher mean internal temperatures in the shielded group maintained the bees in a more active state, enhancing their defensive capabilities against wasp attacks. In contrast, control colonies transitioned into a more compact cluster, potentially reducing their ability to defend themselves against intruders. Notably, one control colony was destroyed within a single day. Consequently, for the overwintering period, the study cohort was reduced to three control and four shielded colonies.

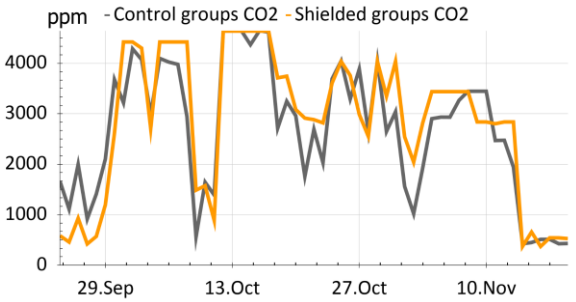


During the cluster formation period, the mean RH of the control group was 72.3 ± 8.5%, which differed significantly (p = 0.004) from that of the shielded group (68.1 ± 10.2%) (Figure 4).

The higher RH variability in shielded hives may stem from the foil's rapid thermal response or altered honeybee ventilation behaviour. In the control group, RH exhibited a significant negative correlation with ambient temperature, particularly T_{min} (r = –0.58). Conversely, this correlation was statistically

insignificant in the shielded group, suggesting that the shielding acts as a moisture buffer against external temperature fluctuations.

Figure 4



RH fluctuations in the control and shielded groups (%)

No statistically significant differences in CO_2 levels were observed between the control (2853.17 ± 1410.49 ppm) and shielded (2811.38 ± 1448.71 ppm) groups ($p = 0.9108$) (Figure 5).

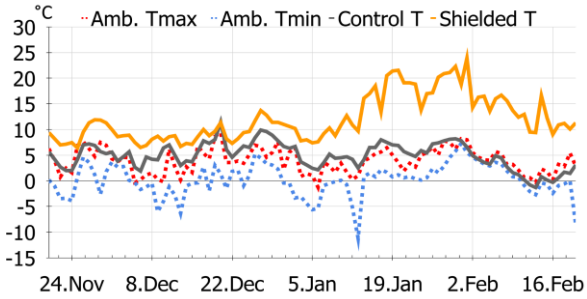
Figure 5

CO_2 fluctuations in the control and shielded groups (ppm)

In the control group, CO_2 showed a significant negative correlation with T_{max} (r = –0.4136) and T_{min} (r = –0.3180), aligning with expectations that metabolic heat production increases as temperatures drop (Kovac et al., 2007; Meikle et al., 2022). This negative correlation was stronger in the shielded group (T_{max} r = –0.4862; T_{min} r = –0.4280), suggesting that shielding may influence CO_2 retention or metabolic intensity.

The overwintering period began on 20 November 2024 and ended on 5 March 2025, when the ambient temperature reached 10 °C. During this period, mortality occurred in two control colonies and one shielded colony. The only surviving control colony was in a weakened state.

Mortality within the shielded group occurred on 3 January (T_{max} = 0.9 °C and T_{min} = –3.1 °C). Although honeybees remained in a cluster, the presence of dysentery symptoms on the combs suggests a pathological cause, likely *Nosema* infection. Consequently, this loss was likely stochastic rather than a direct consequence of the shielding treatment.



Conversely, the control colony losses occurred during periods of relatively mild ambient temperatures. One colony died on 3 December (T_{max} = 4.6 °C and T_{min} = 2.8 °C). The other colony died on 30 January (T_{max} = 6.2 °C and T_{min} = 5.8 °C). In both cases, the absence of a cohesive cluster and the scattering of dead honeybees across the grid suggest a failure of cluster thermoregulation, leading to colony collapse.

While the survival of only one control colony precluded statistical analysis, continuous monitoring of this colony provided observable trends for a detailed qualitative assessment.

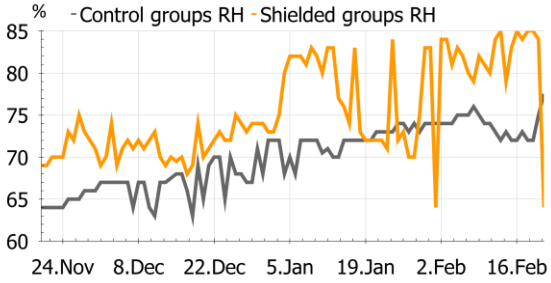
Since interruptions in data transmission occurred from January 21 to March 5 2025, it is not possible to precisely determine temperature differences between the control hive and the shielded group. However, when calculating T_{max} and T_{min} without the missing data, the difference between the control hive and the shielded group was statistically significant ($p < 0.001$). The surviving control hive maintained an average daily temperature of 5.2 ± 2.3 °C, while in the shielded group it averaged 11.9 ± 4.2 °C (Figure 6).

Figure 6

Fluctuations of apiary T_{max} and T_{min}, and T_{mean} of the control hive and shielded group (°C)

The observed mean temperature difference between the groups was 6.7 °C, which was both statistically significant ($p < 0.001$) and biologically significant. Shielding effectively reduced heat losses, which is consistent with the operating principles of aluminium foil as a radiation barrier.

The elevated temperatures (20–25 °C) observed in the shielded hive between 19 January and 2 February (Figure 6) directly demonstrate the effect of the thermoreflective shielding. The shielding enabled the internal ambient temperature to stabilise above 10 °C, a critical threshold that triggered the queen to resume egg-laying. In contrast, the unshielded hive failed to reach this temperature during the same period. Once early brood rearing started, the winter cluster had to maintain a central core temperature of approximately 34.5 °C. The cluster then became stationary to prevent the chilling the brood, even at the risk of starvation (Döke et al., 2015; Minaud et al., 2024; Tautz et al., 2003). Thus, the sustained 20–25 °C readings did not indicate a cluster randomly moving over the sensor, but rather reflected the stable peripheral heat generated by a stationary, brood-rearing cluster that was facilitated by



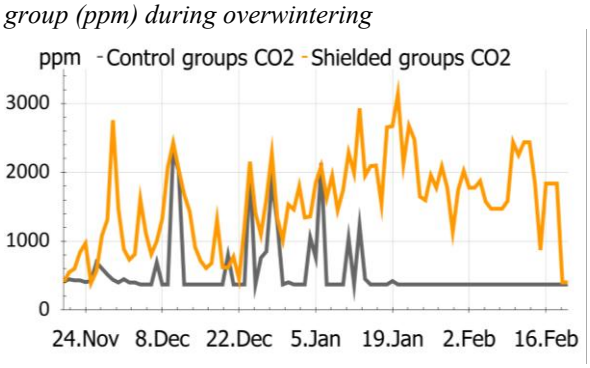
the shielding.

As shown in Figure 6, the control hive's inner temperature closely followed that of the ambient T_{max} and T_{min}, indicating that the control hive was subjected to the influence of external environmental conditions. In contrast, in the shielded group, the correlations with ambient T_{max} ($r = 0.57$) and T_{min} ($r = 0.47$) were moderate, indicating that shielding's insulating effect reduced heat losses and mitigated the external environment's impact on the hive microclimate.

The mean RH in the control hive was 68.60 ± 3.87%, whereas in the shielded group, it was significantly higher ($p < 0.001$), reaching 74.52 ± 4.87% (Figure 7).

Figure 7

RH fluctuations of the control and shielded groups (%) during overwintering



The higher RH in the shielded group may result from the aluminium foil's water-impermeability, which traps metabolic moisture. The correlation between RH and apiary temperatures was negligible (T_{max} $r = 0.034$; T_{min} $r = –0.088$). This independence from external temperature fluctuations suggests that honeybees can actively regulate the microclimate of their hive.

The shielded group exhibited significantly higher CO_2 concentration compared to the control hive ($p < 0.000001$) (Figure 8). Mean levels reached 1517.6 ± 691.2 ppm in the shielded group, whereas the control hive remained at 551.9 ± 512.1 ppm, indicating that shielding substantially elevated internal CO_2 concentrations during overwintering.

In the shielded group, CO_2 levels exhibited significant weak negative correlations with both T_{max} ($r = –0.221$, $p = 0.032414$) and T_{min} ($r = –0.370$, $p = 0.000288$). This inverse relationship suggests that the foil barrier not only passively increased CO_2 levels but also modulated the colony's dynamic respiratory response to external thermal fluctuations. As the ambient temperature decreased, the widening temperature gradient accelerated heat loss. To compensate, honeybees increased honey consumption, accelerated metabolism, and formed a tighter cluster, inherently elevating CO_2 production.

Figure 8

CO_2 fluctuations of the control hive and shielded group (ppm) during overwintering

The foil barrier likely suppressed convection and retained the metabolic heat and CO_2 more efficiently than in the control hive. Consequently, the shielded group showed a more pronounced increase in CO_2 as the external temperature decreased, indicating that shielding enhanced thermal stability and significantly improved overwintering survival rates.

Conclusions

1. Thermoreflective shielding is an effective method for enhanced colony viability amid changing climatic conditions. By mitigating overwintering stress, shielding resulted in a markedly lower mortality rate.
2. During the cluster formation period, shielding ensured more uniform cooling within the hive. This gradual transition to the overwintering regimen extended the period for late-season brood development and food storage, while also enabling the colonies to defend more effectively against autumn wasp attacks.
3. During the overwintering, shielding substantially reduced heat loss, maintaining cluster temperatures an average of 6.7 °C higher than the control hive. This thermal stability lowered the metabolic demands of thermogenesis, thereby reducing food consumption and mitigating the risk of late-winter starvation.
4. In addition to heat retention, the shielding protected winter clusters from premature activation during brief thaws, which could lead to higher mortality when frosts return. Shielding also improved moisture control by minimising internal condensation.
5. Because the high mortality rate within the control group precluded comprehensive statistical analysis, the current findings primarily represent strong observational trends. To robustly validate observed outcomes and definitively attribute them to the thermoreflective surfaces, future studies must incorporate larger sample sizes, requiring at least six hives per experimental group.

Abstract
Methane (CH_4) is a significant greenhouse gas emitted by livestock. The study aimed to investigate compliance or differences between calculated and measured CH_4 emissions on a high-productivity 900-head Holstein Friesian (HF) cow farm. Data from two feeding programs (NorFor and AMTS Pro) and on-farm CH_4 measurements using the Methane Detector-Transmitter E2608-CH_4 (Evikon, Estonia) were used. The feed program NorFor predicted a CH_4 output of 652 g per cow^{-day}. However, with AMTS Pro, the amount was determined to be 828 g per cow^{-day} ($p < 0.05$). The measured on-farm CH_4 values were 810.5±229.81 g^{-day}, and they ranged from 648 to 973 g^{-day} per cow ($p<0.05$). Feeding programs and generally accepted calculation methods assume that an HF cow weighs around 600 kg, but on our farm, there was a wider range of live weights of cows (up to 1100 kg). On-farm measurements could also depend on parameters, such as the cow's lung volume and respiratory rate, which can vary with ambient temperature and humidity. In conclusion, because the calculated values span a wide range based on theoretical parameters, measuring CH_4 concentration at specific times using sensors provides greater accuracy. Furthermore, this method enables the real-time monitoring and reduction of CH_4 emissions through targeted management and feeding adjustments. Consequently, sharing these empirically verified results demonstrates a commitment to transparency, which is a key element of credible sustainability communication with stakeholders and the public.
Keywords: enteric methane, GHG, dairy cattle, precision livestock farming, sustainability communication.

Introduction

Livestock agriculture is one of the major sources of greenhouse gas (GHG) emissions, with enteric fermentation accounting for nearly 90% of CH_4 emissions. Given its high global warming potential, accurate quantification of CH4 is essential for effective climate change mitigation strategies (Ghassemi Nejad et al., 2024). Methane is a significant contributor to the greenhouse effect and global warming and has been a hot topic in recent decades, especially in the livestock sector (Our World in Data, 2026). The Greenhouse Gas Protocol was developed by the World Business Council for Sustainable Development, in collaboration with the World Resources Institute (The Greenhouse Gas Protocol, 2004). It includes two important related standards: The Emissions Protocol Corporate Accounting and Reporting Standard, which provides companies with guidance on measuring greenhouse gas (GHG), and the Emissions Protocol Project Quantification Standard. Based on these frameworks, GHG calculation methods are widely accepted in many agricultural sectors, including livestock (Greenhouse Gas Protocol, 2026).

In general, CH_4 estimation approaches fall into three main categories: direct measurement techniques at the facility level, indirect inventory-based models using emission factors, and remote sensing methods for large-scale detection (Ghassemi Nejad et al., 2024). The Intergovernmental Panel on Climate Change (IPCC) defines three methodological tiers for national GHG reporting, with the highest tier relying on direct measurements to develop country-specific emission factors and requiring robust verification systems (IPCC, 2019). This also highlights the need for locally measurement-supported emission factors to improve national CH_4 inventories and support effective emission-reduction measures that are essential for meeting UNFCCC (United Nations Framework Convention on Climate Change), Kyoto Protocol, and EU climate and air quality targets (Amon et al., 2021). The desire to maintain a positive reputation and navigate social pressures can inadvertently lead to biased sustainability reporting (Steiner et al., 2018). Understanding and accurately communicating the true environmental impact of dairy production is an essential prerequisite for sustainable livestock management and transparent sustainability reporting.

Until now, in practical livestock farming, direct emission measurements have not been widely carried out. Emissions have typically been measured using specialized equipment in scientific studies (Tedeschi et al., 2022). However, invasive measurement techniques are often not feasible in practical farming due to welfare standards. Since GHG emissions depend on well-known individual factors, there is a lack of precise data on how closely the calculated values reflect each farm's specific situation. Moreover, there are currently no tools for herd owners to monitor or influence their animals' emissions. Consequently, farmers lack practical, data-driven ways to reduce emissions and transparently report their progress. Without direct monitoring, there is no way to track emissions dynamics or understand the correlations with specific management factors that the owner can influence. Bridging this data gap provides a robust evidence base for effective stakeholder management and authentic sustainability communication. By aligning theoretical calculations with real-time measurements, farmers can provide transparent, credible data for reporting, thereby mitigating the risks of social desirability bias and fostering long-term trust with stakeholders. This data gap is particularly critical in the context of the UN Sustainable Development Goals and has become a key benchmark for practical

action by governments, NGOs (Non-governmental organisations), and entrepreneurship (including farmers). Sustainability is normatively defined not only by environmental protection and responsibility toward future generations, but also through active participation, characterized by specific, measurable actions and transparent communication (Weder et al., 2019).

Future work should focus on strengthening country-specific data collection and refining emission models through comparative studies that integrate measured data (Besson et al., 2026). Because mitigation effectiveness varies by region and production system, accurate, locally calibrated emission factors and a deeper understanding of how inventories influence policy decisions are essential for reliable climate planning and achieving meaningful agricultural GHG reductions (Nugrahaeningtyas et al., 2024). Effective livestock CH_4 mitigation relies on accurate measurement technologies, robust data systems, and system-wide changes across the agri-food chain (Bretscher et al., 2025). Therefore, this study aimed to compare the measured and predicted CH_4 amounts from feeding programs on a high-producing dairy farm. To achieve the goal, two feeding programs and practical measurements were carried out to process statistical data for comparison and to assess their correspondence. This is necessary to obtain data for future research that would allow us to understand how the amount of CH4 emitted on a dairy farm can be monitored and influenced. Demonstrating a proactive commitment to continuous environmental improvement is a foundational element of credible sustainability communication with stakeholders (Bittner-Fasseler & Weicht, 2020). The methodology and format used to present emission data are as vital as the content itself, directly influencing how stakeholders perceive the value of emission-reduction efforts, which ultimately fosters sustainable progress (Liu et al., 2025).

Materials and Methods

The study was conducted in a high-producing HF dairy herd of more than 900 animals during the summer of 2025. The annual milk yield in the previous year was more than 14,000 kg per cow. A freshly prepared, total mixed ration (Table 1) was distributed once a day and replenished to the cows three times a day. To ensure maximum even feed intake and cows' interest in feed, feed is pushed closer to the cows once an hour. The animals included in this study received identical feed composition.

The farm manager records the amount of feed distributed and the surplus remaining in each cow group (about 500 kg^{-day}). Drinking water was provided *ad libitum* in collective automatic drinkers. Due to high productivity, cows are milked three times a day in a rotary milking carousel (PR3100HD DeLaval, DelPro system, Sweden).

Feces and urine were removed from cow groups three times a day while the cows were being moved to the milking waiting area before the milking carousel (PR3100HD, DeLaval, Sweden). The farm uses sand bedding, which is changed once a week. To ensure better air quality and an optimal indoor temperature, the forced ventilation system is automatically set to 14 °C during the summer. An automatic water-spraying system is set to activate at 22 °C. Cows are given hoof care twice a year.

Table 1

Feed composition in the study period

No	Parameter	Amount in May
1.	Dry Matter Intake predicted per cow (kg^{-day})	27.22
2.	Dry Matter (%)	44.92
3.	Forage (%DM)	52.01
4.	Crude Protein (%)	17.33
5.	Starch (%DM)	25.07
6.	Sugar (%DM)	5.29
7.	Neutral detergent Fibre (%DM)	27.32
8.	Acid Detergent Fibre (%DM)	17.49
9.	Nonfibrous carbohydrates (%DM)	43.09
10.	Energy-corrected milk (kg^{-day})	51.81
11.	Predicted Milk Production (kg^{-day})	47.55
12.	Rumen pH predicted	27.22

This research was conducted on cows before the dry period and 120 days after calving. Measurements were taken on 21 multi-lactations and 45 first-lactation cows. The cows varied in their days in milk. CH_4 and CO_2 measurements were taken during the hoof trimming process, which lasted 6-10 minutes depending on the particular cow's hoof length and health status.

Calibrated Detector-Transmitters E2608-CO2-10K and E2608-CH4 were used to measure CO_2 and CH_4 concentration in cows' breath/burp. CO_2 was measured for CH4 calculation reasons. Sensors were set up and calibrated in accordance with ISO 9001:2015 quality management system requirements. Data were collected every 5 seconds. The CH_4 (and parallel CO_2) measurements were taken once a month in June, July and August. An average CH_4 data value was used because feeding programs predicted the same value each month. This was done one week to 10 days after the feed recipe was changed due to farm conditions. Feed changes were insignificant given the same dry matter intake and energy capacity.

Two feeding programs (NorFor and AMTS Pro) were used to calculate potential CH_4 production from one cow^{-day}.

The CH4 output from cows was calculated using data on CO2 and CH4 obtained (Madsen et al., 2010). The formula (1) was:

$$\text{CH4 output}\left(\frac{\text{L}}{\text{day}}\right) = a \times \frac{b-d}{c-e} \qquad (1)$$

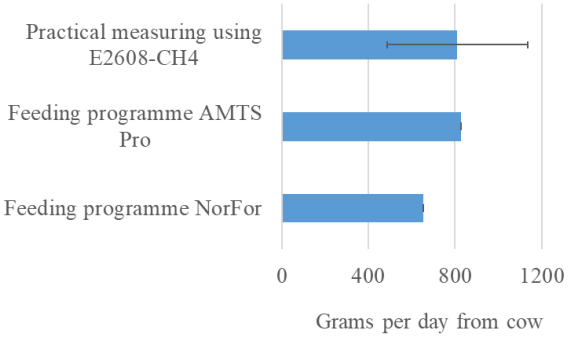
In which: a means the CO2 exhaled by the cow (L^{-day}); b is the concentration of CH4 in the gas mix exhaled (ppm); c is the concentration of CO2 in the ambient air mix (ppm); d is the concentration of CH4 in the barn air (ppm); e is the concentration of CO2 in the barn air (ppm).

To calculate CH_4 L to grams, CH_4 volume was converted to mass using the fact about a density of 0.68 g L^{-1} at standard conditions (15 °C, 101.325 kPa) and the molar mass of CH_4 (16.04 g/mol). For example, 500 $L^{-day} \rightarrow 500 \times 0.68 = 340 g/day$. A similar approach was done by Bell et al. (2014). A data logger was used to collect and store the data obtained. Data was transferred from a flash drive to a computer. The software *FieldLoggerConfig* was used to take data from the flash drive. CH_4 concentrations in the exhaled breath/burp were recorded in LEL% (Lower Explosive Limit) and transformed to ppm (particles per million). The LEL is considered the minimum concentration of flammable gas or vapour in air that can cause a sudden appearance of flame. On a 0–100% scale, 100% LEL is the threshold at which a gas mixture becomes flammable, and for CH_4, the LEL in air is 5% by volume. It is a crucial safety measure to prevent or avoid explosions. Subsequently: - 100% LEL = 5% vol CH_4 = 50,000 ppm; - 10% LEL = 0.5% vol = 5,000 ppm; - 1% LEL = 0.05% vol = 500 ppm. And because of this, the formula (2) is:

$$ppm = \%\ LEL\ x\ 500, \qquad (2)$$

where *ppm* – particles per million; *LEL* - Lower Explosive Limit.

To estimate CH_4 emissions (L day^{-1} cow^{-1}), the previously used formula (Madsen et al., 2010) has been adopted by other researchers (Negussie et al., 2017). Microsoft Excel and IBM SPSS Statistics 21 were used for statistical analysis (Arhipova et al., 2006). Because the main CH4 is produced in the rumen and expelled by burping, it is acceptable to compare calculated values from programs with measured CH4 values (Bačėninaitė et al., 2022).



An average, standard deviation, bivariate correlation (body weight and CH_4 amount) and the One-sample t-test were used to compare feeding program results with practical measurement data. A statistically significant difference was recognized if the *p*-value was less than *0.05*.

Results and Discussion

The measured on-farm CH_4 values were 810.5±229.81 g^{-day} and ranged from 648 to 973 g^{-day} per cow ($p<0.05$), indicating considerable individual variation. An individual cow's CH4 emission was also noticed by other scientists (Bell et al., 2014). Based on the current feed recipe, the feed program NorFor predicted a CH_4 output of 652 g per cow per day, which was statistically significantly lower than the CH_4 output measured in practical measurements using sensors ($p<0.05$). In contrast, with AMTS Pro, the amount was determined to be 828 g per cow per day, which was statistically higher than the results obtained with the NorFor feeding program and practical measurements ($p<0.05$; Figure 1). Calculated values were similar in all three months for the AMTS Pro feeding programme. So, the NorFor calculation was conducted just in May. It would be advisable to monitor CH4 levels on farms to gauge a specific company's sustainability performance.

Generally, feeding programs and accepted calculation methods assume that an HF cow weighs around 600 kg, but on our farm, there was a wider range of live weights (640 kg, up to 1100 kg). Cow bodyweight did not correlate with CH_4 output nor rumination time ($p>0.05$). The same result was obtained by other scientists (Bell et al., 2014). On-farm measurements also could depend on parameters, such as the cow's lung volume and respiratory rate, which can vary with ambient temperature and humidity (Gallivan et al., 1989).

Figure 1
Methane emissions per cow

These criteria regarding pulmonary capacity were investigated quite some time ago; in contrast, CH4 production was reported not to correlate with cow body weight (Oikawa et al., 2025). The amount of GHG emitted by cows depends on the composition and amount of feed consumed; relying solely on standard calculations based on the same feed highlights the wide generalisation of these models and does not allow for the timely identification and breeding of animals that emit less GHG.

The data suggests a need to re-evaluate internal corporate actions and processes for implementing and communicating sustainability. This shift is essential to overcome specific barriers hindering local-level sustainability. Furthermore, despite a generally positive disposition towards sustainability, enterprises frequently fail to allocate sufficient time and energy to translate internal intent into measurable actions (Serttas et al., 2022). This highlights two primary challenges. First, for farmers and SMEs (small and medium-sized enterprises), it is a struggle to translate gathered data into actionable insights, indicating a need for effective sustainability communication tools and perhaps an external 'translator'; secondly, farmers' (and SMEs') sustainability strategies are

strongly linked to implicit attitudes (Steiner et al., 2018; Aliyev, 2025).

Conclusions

1. The incomparability is proven if data are obtained using different feeding programs to calculate CH_4 emitted by cows, as well as by in vivo measurement.
2. Since different amounts of CH_4 emissions were found in cows with the same diet, further research is needed on the influence of individual factors.
3. Different live weights of cows are not a significant factor in the amount of CH_4 emitted from cows. Perhaps the answer should be sought within the physiological limits of CH4 release, such as genetic factors.
4. On-farm monitoring would allow tracking individual emission dynamics and accounting for specific herd circumstances, whereas standard calculation methods offer only generalised predictions. The precision of this data is vital for stakeholder transparency, as the accuracy of environmental reporting is just as important as the content for fostering sustainable progress and maintaining robust sustainability communication.
5. The findings indicate a deficiency in understanding how to apply emission data to the decision-making and communication processes, reinforcing the need for small enterprises to bridge the gap between internal sustainability intent and measurable action.

Abstract
The formation of biomass in perennial energy crops requires optimization of agronomic practices to ensure high productivity and efficient use of agricultural land for bioenergy purposes. Switchgrass (*Panicum virgatum* L.) is considered a promising lignocellulosic energy crop; however, its biomass yield and energy potential largely depend on cultivation conditions, particularly during the establishment phase. The aim of this study was to assess the effect of sowing date and seed burial depth on biomass yield and energy potential of switchgrass in the Forest-Steppe zone. Field experiments were conducted using different sowing dates and seed burial depth variants. Biomass yield and energy output per unit area were evaluated based on the obtained experimental data. The results showed that early sowing combined with a seed burial depth of 1.0–1.5 cm ensured the highest biomass yield. The maximum average biomass yield reached 11.9 t ha^{-1}, which corresponded to the highest solid biofuel yield and energy output of 386.83 GJ ha^{-1}. A gradual increase in biomass productivity was observed from the first to the third year of vegetation, confirming the biological characteristics of switchgrass as a perennial crop. The findings demonstrate that optimization of agronomic parameters is an effective tool for managing the biomass yield potential of switchgrass and increasing the energy potential of agricultural land used for bioenergy production.
Keywords: agronomic management, bioenergy crops, biomass productivity, planting depth, bioenergy.

Introduction

The growing demand for renewable energy sources stimulates the search for sustainable biomass resources capable of providing stable energy supply. The implementation of energy-efficient technologies and renewable energy systems is also consistent with the principles of the European Green Deal aimed at sustainable industrial and agricultural development (Hutsol, 2023). Lignocellulosic energy crops are considered one of the most promising feedstocks for solid biofuel production due to their high productivity, environmental benefits, and ability to grow on marginal lands (McLaughlin & Kszos, 2005; Wright & Turhollow, 2010).

Among such crops, switchgrass (*Panicum virgatum* L.) occupies a leading position as a perennial C4 grass with high biomass productivity, broad ecological adaptability, and relatively low cultivation costs (Moser & Vogel, 1995; McLaughlin & Kszos, 2005; Mitchell et al., 2008; Parrish & Fike, 2009). Switchgrass has been widely studied as a bioenergy crop due to its ability to produce large amounts of lignocellulosic biomass suitable for biofuel production systems (Vogel et al., 2011). Long-term field studies demonstrate the stability of switchgrass biomass yield and its suitability for large-scale bioenergy production (Fike et al., 2006).

The productivity of switchgrass largely depends on agronomic management practices, including fertilization, planting density, harvesting regimes, and stand age (Monti et al., 2008; Muir et al., 2001; Wolf & Fiske, 2009). Proper management of these factors makes it possible not only to increase biomass yield but also to improve the structural characteristics of plant material important for subsequent conversion processes (Frank et al., 2004; Sharma et al., 2022).

From an engineering perspective, the quality and energy potential of biomass are determined not only during post-harvest processing but also at the stage of crop cultivation. Agronomic parameters influencing plant development can significantly affect biomass accumulation and its technological characteristics during further processing (Flint et al., 2021; Mosier et al., 2024).

In addition, the development of sustainable bioenergy systems requires the integration of agronomic management with broader bioeconomy strategies and renewable energy development frameworks (Kucher et al., 2024). In this context, energy crops such as switchgrass, miscanthus, and energy willow are considered important components of future biomass supply chains (Nedilska et al., 2023; Yermakov et al., 2023a, 2023b).

Despite the considerable number of studies devoted to the productivity of energy crops, the issue of effective management of biomass yield potential under different agronomic conditions remains relevant. Therefore, the aim of this study was to evaluate the influence of selected agronomic practices on the biomass yield potential of switchgrass (*Panicum virgatum* L.) as an energy crop.

Materials and Methods

Experimental site and conditions

Field experiments were conducted during 2022–2024 at the experimental fields of Higher educational institution 'Podillia State University' located in the Western Forest-Steppe of Ukraine. The region is characterized by a moderately continental climate with warm summers and relatively mild winters.

The soil of the experimental site was typical chernozem with medium loamy texture. Before establishing the experiment, soil samples were analyzed to determine the main agrochemical properties, including humus content, available nitrogen, phosphorus, and potassium. The soil

of the experimental field was deep low-humus heavy loam chernozem formed on loess-like loams. The main agrochemical properties of the soil layer (0–30 cm) were as follows: humus content 4.34 %, soil pH 6.8, easily hydrolyzed nitrogen 124 mg kg^{-1}, available phosphorus 86 mg kg^{-1}, and exchangeable potassium 167 mg kg^{-1}. Such soil characteristics are generally considered suitable for the cultivation of perennial energy crops, including switchgrass (*Panicum virgatum* L.).

Figure 1
Switchgrass for the growing season

The vegetation period of the crop was determined as the interval between the dates when the average daily air temperature exceeded 5 °C in spring and dropped below this threshold in autumn. The thermal regime during the study years was characterized by the sum of active temperatures, which reflects the total heat available for plant growth.

During the research period, weather conditions differed between years. In April 2022, the average air temperature was 8.6 °C, which was relatively low for rapid seed germination. In contrast, April 2023 was significantly warmer, with an average temperature of 14.5 °C, which created more favorable conditions for crop establishment. In April 2024, the average temperature was 10.2 °C.

The temperature conditions in May also differed between years. In 2022, the average temperature was 14.0 °C, which contributed to satisfactory seed germination. In 2023, the temperature reached 17.9 °C, which was the highest during the study period, whereas in 2024, it was 15.2 °C. The long-term average sum of active temperatures above 5 °C in the region is about 2990 °C and above 10 °C about 2660 °C.

Precipitation during the study years also varied considerably. In 2022, the amount of precipitation in April was 35.5 mm and decreased to 26.7 mm in May. The lowest precipitation was observed in April 2023 (16 mm), while in May of the same year, it exceeded 31 mm. The total annual precipitation that year reached 564 mm. In 2024, the amount of precipitation in April was 52 mm, while in May it reached 100 mm, which had a significant effect on the formation of switchgrass biomass productivity.

Experimental design

The field experiment was designed to evaluate the influence of selected agronomic practices on the biomass productivity of switchgrass.

The following experimental factors were studied:

Factor A – sowing time:

1. early sowing - third decade of April;
2. optimal sowing - first decade of May;
3. late sowing - second decade of May.

Factor B – seed burial depth:

1. 0.5–1.0 cm;
2. 1.0–1.5 cm;
3. 1.5–2.0 cm.

The experiment was established using a sequential arrangement of treatments with three replications. The total experimental area consisted of multiple plots where each treatment combination was represented in each replication.

The experimental design allowed assessment of both the individual and combined effects of sowing time and seed placement depth on the growth and productivity of switchgrass.

Agronomic management practices during the experiment corresponded to the generally accepted cultivation technologies for perennial energy crops. Before sowing, the experimental plots were prepared using conventional soil preparation practices to create a suitable seedbed for small seeds.

Sowing was carried out according to the experimental design during the first, second, and third ten-day periods of April depending on the treatment. Seeds of switchgrass were sown manually within the research plots. The seeding rate was 6 kg ha^{-1} of viable seeds. During the establishment period, crop management included manual weed control and maintenance of optimal soil moisture conditions through periodic irrigation when necessary.

Biomass harvesting was carried out at the end of the growing season (Nadykto et al., 2023). Plants were cut manually close to the soil surface within the accounting area of each experimental plot. The accounting area was 6 m^2. The harvested biomass from each plot was weighed to determine yield per unit area.

Measurements and observations

Observations and measurements during the growing seasons included plant development stages, stand density, and biomass accumulation.

Biomass yield was determined at the end of the vegetation period by harvesting plants from the accounting plots followed by weighing and recalculation per hectare. Dry matter content was determined using standard drying procedures.

Field experiments and biometric measurements were conducted according to the generally accepted methodologies for agronomic and biological studies (Hrytsaienko et al., 2003; Volkodav, 2000).

Calculation of biomass and energy yield

The potential yield of solid biofuel from switchgrass biomass was determined using a calculation approach based on biomass productivity and fuel characteristics.

The yield of solid biofuel was determined using the following Equation 1:

$$T = U \cdot c \cdot (1 - w) \quad (1)$$

where:
T – yield of solid biofuel, t ha⁻¹;
U – biomass yield, t ha⁻¹;
c – dry matter content coefficient;
w – fuel moisture content.

Such approaches are commonly used for evaluating the energy potential of biomass crops and estimating their suitability for bioenergy production systems (Vogel et al., 2011).

Statistical analysis

Experimental data were processed using standard statistical methods applied in agronomic research. The significance of treatment effects was evaluated using analysis of variance (ANOVA).

Statistical processing of experimental results was carried out following the methodological recommendations for agricultural experiments (Hrytsaienko et al., 2003; Volkodav, 2000).

Results and Discussion

Weather conditions during the experimental years differed in temperature and precipitation, which influenced biomass formation in different years.

During the three-year experimental period, switchgrass biomass yield was evaluated depending on sowing date and seed burial depth.

Overall, the highest average biomass yield among the studied variants was obtained for the first sowing date with a seed burial depth of 1.0–1.5 cm, reaching 11.9 t ha⁻¹. Slightly lower yields were recorded when the seed burial depth was 1.5–2.0 cm (11.6 t ha⁻¹). When the seed burial depth was reduced to 0.5–1.0 cm, biomass yield reached 11.3 t ha⁻¹. According to the LSD05 values, the influence of sowing date and seed burial depth on biomass yield was statistically significant.

Table 1

*Biomass yield of switchgrass depending on sowing date and seed burial depth**

Sowing time	Burial depth, cm	1st year	2nd year	3rd year	Average yield, t ha⁻¹
I	0.5-1.0	6.4	12.1	15.4	11.3
	1.0-1.5	6.9	12.6	16.1	11.9
	1.5-2.0	6.6	12.4	15.8	11.6
II	0.5-1.0	6.1	11.2	14.8	10.7
	1.0-1.5	6.5	11.8	15.3	11.2
	1.5-2.0	6.3	11.5	15.1	10.9
III	0.5-1.0	5.8	10.2	14.4	10.1
	1.0-1.5	6.3	10.6	15.0	10.6
	1.5-2.0	6.0	10.4	14.7	10.3
	LSD05 A 0.1 B 0.13 AB 0.12				

*Differences exceeding LSD05 values were considered statistically significant.

The biomass yield obtained during the second sowing period was generally lower than that of the first sowing period. The highest yield in this group was observed at a burial depth of 1.0–1.5 cm, where biomass production reached 11.2 t ha⁻¹. Other variants of seed burial depth produced slightly lower yields: 10.9 t ha⁻¹ at 1.5–2.0 cm and 10.7 t ha⁻¹ at 0.5–1.0 cm.

The third sowing date produced the lowest biomass yield among the analyzed variants. In this case, the yield reached 10.6 t ha⁻¹ at a seed burial depth of 1.0–1.5 cm, 10.3 t ha⁻¹ at 1.5–2.0 cm, and 10.1 t ha⁻¹ at a depth of 0.5–1.0 cm.

The obtained differences between the studied variants exceeded the LSD05 values, confirming their statistical significance.

The total biomass yield for the entire experimental period was highest for the first sowing date and ranged from 33.9 to 35.6 t ha⁻¹ depending on seed burial depth. The highest value was obtained at a depth of 1.0–1.5 cm. The second sowing date produced slightly lower yields, with a maximum value of 33.6 t ha⁻¹. The lowest yields were observed for the third sowing date, where the maximum value reached 31.9 t ha⁻¹.

Because switchgrass is a perennial crop, vegetation resumed in subsequent years, and biomass yield increased annually as the plants became better established. The highest yield values were observed in 2024, which corresponded to the third year of crop growth.

The highest yield in 2024 (16.1 t ha⁻¹) was obtained for the first sowing date at a seed burial depth of 1.0–1.5 cm. Slightly lower yields were observed at depths of 1.5–2.0 cm (15.8 t ha⁻¹) and 0.5–1.0 cm (15.4 t ha⁻¹).

The second sowing date produced somewhat lower yields. The highest value was 15.3 t ha⁻¹ at a burial depth of 1.0–1.5 cm. At depths of 1.5–2.0 cm and 0.5–1.0 cm, biomass yield reached 15.1 and 14.8 t ha⁻¹, respectively.

The third sowing date in 2024 showed the lowest yield values among the studied sowing periods. The highest yield was 15.0 t ha⁻¹ at a burial depth of 1.0–1.5 cm, while the other variants produced 14.7 and 14.4 t ha⁻¹, respectively.

The final indicator characterizing the efficiency of switchgrass cultivation is the yield of solid biofuel and the corresponding energy output. Based on biomass productivity data, the yield of solid biofuel and energy was calculated (Table 2). The dry matter content of switchgrass biomass was determined experimentally using the gravimetric method and averaged 52%.

The highest solid biofuel yield (20.91 t ha⁻¹) and energy output (386.83 GJ ha⁻¹) were obtained for the first sowing date at a seed burial depth of 1.0–1.5 cm.

The results of the study demonstrated that sowing date and seed burial depth significantly influence the formation of switchgrass biomass and its suitability for further energy use. Early sowing created more favorable conditions for plant establishment, which contributed to higher biomass productivity and more uniform plant structure.

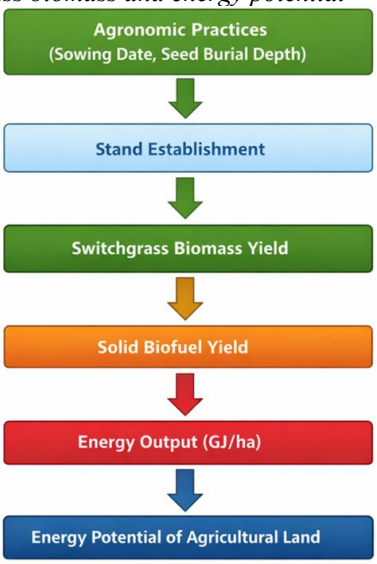
The optimal seed burial depth was 1.0–1.5 cm, which ensured favorable conditions for seed germination and early plant development. Both deeper and shallower seed placement resulted in lower plant density and reduced biomass yield and energy potential per unit area.

Table 2

*Switchgrass biomass yield and calculated solid biofuel and energy output depending on sowing date and seed burial depth (total for 2022–2024)**

Sowing time	Burial depth, cm	Total biomass yield, t ha^{-1}	Solid biofuel yield, t ha^{-1}	Energy yield, GJ ha^{-1}
I	0.5-1.0	33.9	19.91	368.33
	1.0-1.5	35.6	20.91	386.83
	1.5-2.0	34.8	20.44	378.14
II	0.5-1.0	32.1	18.86	348.91
	1.0-1.5	33.6	19.74	365.19
	1.5-2.0	32.9	19.33	357.60
III	0.5-1.0	30.4	17.86	330.41
	1.0-1.5	31.9	18.74	346.69
	1.5-2.0	31.1	18.27	337.99

*LSD05 values are presented to indicate statistically significant differences between treatments at $p \leq 0.05$.



The obtained results demonstrate that agronomic practices play a key role in the formation of switchgrass biomass productivity and, consequently, in the energy potential of cultivated areas. Similar observations were reported by Parrish & Fike (2005), who emphasized that successful establishment during the early stages of switchgrass development is one of the key factors determining long-term biomass productivity. Mitchell et al. (2008) also noted that agronomic management practices significantly influence the stability and productivity of switchgrass biomass production systems. The relationship between agronomic management practices, biomass formation, and energy yield is conceptually presented in Figure 2. The conceptual scheme presented in Figure 2 illustrates the sequence of processes linking agronomic management practices with the formation of biomass yield and the resulting energy potential of switchgrass cultivation.

Agronomic factors such as sowing date and seed burial depth significantly influenced switchgrass establishment and biomass productivity in the present study. Similar observations were reported by Parrish & Fike (2005), who emphasized the importance of successful crop establishment for long-term biomass formation in switchgrass cultivation systems. Mitchell et al. (2008) also noted that agronomic management practices play an important role in maintaining stable biomass productivity of perennial bioenergy crops. In the present study, optimization of sowing parameters contributed to increased biomass yield and energy output per unit area.

Early sowing allows plants to utilize soil moisture accumulated during the winter period and ensures more favorable temperature conditions for seed germination and early plant development. Similar conclusions were reported by Parrish & Fike (2005), who noted that the successful establishment of switchgrass crops largely depends on sowing conditions during the initial growth stages.

Figure 2

Conceptual scheme of agronomic management of switchgrass biomass and energy potential

The results obtained in this study also demonstrate that inappropriate seed burial depth may negatively affect plant emergence and stand density. Seeds placed too shallow may suffer from insufficient soil moisture, while deeper placement may delay germination and reduce plant emergence. The optimal burial depth of 1.0–1.5 cm observed in this research corresponds with recommendations reported in previous studies on switchgrass cultivation (Mitchell et al., 2008).

The gradual increase in biomass yield during the second and third years of vegetation observed in the experiment is consistent with the biological characteristics of switchgrass as a perennial energy crop. Several studies have demonstrated that maximum biomass productivity is usually achieved after full establishment of the stand, typically in the third or fourth year of cultivation (Fike et al., 2006). The results of the present study confirm this pattern, as the highest biomass yields were recorded in the third year of plant growth. The tendency toward increased biomass productivity during the first years of cultivation is consistent with the findings of Fike et al. (2006), who reported gradual stabilization and enhancement of switchgrass yield potential in perennial production systems.

In addition to agronomic factors, environmental conditions during the growing season also influence biomass accumulation. Variations in temperature and precipitation observed during the experimental years

likely contributed to differences in biomass formation between years. According to Sharma et al. (2022), climatic factors together with agronomic management practices significantly influence biomass yield formation in perennial bioenergy crops such as switchgrass.

The results obtained also confirm that improving agronomic management practices can significantly enhance the energy potential of switchgrass biomass. The calculated solid biofuel yield and energy output demonstrate that optimization of sowing parameters contributes to increased biomass production and consequently higher energy yield per unit area.

Overall, the findings of this study emphasize the importance of optimizing sowing technology for switchgrass cultivation. Proper selection of sowing time and seed burial depth ensures better crop establishment, higher biomass productivity, and improved energy potential of this promising bioenergy crop.

The proposed conceptual approach to managing switchgrass biomass productivity can be applied not only at the field level but also for planning and optimization of bioenergy systems. By adjusting key agronomic parameters such as sowing date and seed burial depth, it is possible to influence biomass yield and, consequently, the energy output per unit area in a predictable manner. According to Sharma et al. (2022), optimization of agronomic factors remains one of the most effective approaches for improving the productivity and bioenergy efficiency of perennial energy crops, including switchgrass.

This creates opportunities for integrating agronomic management decisions into energy planning models, where biomass yield can be considered as a controllable parameter rather than a fixed value. As a result, agricultural land used for switchgrass cultivation can be more efficiently utilized to achieve higher and more stable energy production.

Thus, the management of agronomic practices should be regarded as an essential component of bioenergy system optimization, linking crop production with energy generation efficiency.

Conclusions

1. The results of the conducted research confirm that agronomic management practices play an important role in the formation of switchgrass (*Panicum virgatum* L.) biomass productivity and, consequently, in the energy potential of cultivated areas intended for bioenergy production.
2. It was established that both sowing date and seed burial depth significantly influence the formation of switchgrass biomass. Early sowing created more favorable conditions for plant establishment and development, which contributed to higher biomass yields during the experimental period. At the same time, the optimal seed burial depth was determined to be 1.0–1.5 cm, which ensured better seed germination and uniform plant stand formation.
3. The highest average biomass yield over 3-year study period of 11.9 t ha^{-1} was obtained under the conditions of early sowing combined with a seed burial depth of 1.0–1.5 cm. This variant also provided the highest calculated yield of solid biofuel (20.91 t ha^{-1}) and the highest energy output (386.83 GJ ha^{-1}).
4. Thus, the implementation of scientifically substantiated agronomic practices in the cultivation of switchgrass as an energy crop can significantly improve biomass production efficiency and increase the overall energy yield of agricultural land used for bioenergy purposes.

Abstract
The extent of anthropogenically created and impacted ecosystems is increasing globally, and forest roads can be considered as an example of such ecosystems. Despite their numerous negative impacts on biodiversity, recently, roads have been increasingly recognized for their potential role as habitats for butterflies. This study was aimed at exploring how flowering plant abundance and richness are related to butterfly diversity along forest roadsides. Differences in species richness and abundance were investigated along forest roads subject to different management regimes. Additionally, we assessed the effect of vegetation composition on butterfly diversity. We selected two study sites, representing 25 km of differently managed roadsides. The active sampling line–transect method was used to survey butterflies in the summer of 2024 and 2025. In total, 51 butterfly species were recorded along all studied roads, including six grassland indicator species and two protected species. While the highest species richness and abundance were observed along managed roadsides and roadsides with higher cover of flowering plants, we did not observe higher diversity of butterflies along roads with wider verges. In addition, the managed road verges were represented by plant species from nectar plant families that support high butterfly richness. The current study confirms the importance of maintaining flowering plant diversity on forest road verges.
Keywords: pollinators, forest road verges, managed roadsides, nectar sources.

Introduction

It has been shown that forest roads are expanding (Ring et al., 2024), thus facilitating changes in plant and animal populations, introducing exotic elements, modifying material flows in the area and availability of resources such as water, light and nutrients (Coffin, 2007). Despite their numerous negative impacts on biodiversity (Lugo & Gucinski, 2000), recently roads are increasingly recognized for their potential role as habitats for pollinators (Meinzen et al., 2024). Forest roads that are anthropogenically created landscape structures could serve as dispersal corridors and linear habitats for pollinator species (Phillip et al., 2020). Furthermore, verges along the roads may provide an important place of refuge for pollinators, including butterfly species (Phillip et al., 2020), thus contributing to the maintenance of butterfly species diversity in forested landscape (Schmitt et al., 2024). Butterflies are one of the most important pollinator species groups which are exposed to a global decline in the last decade (Potts et al., 2010; Ulyshen & Horn, 2023), with mostly specialist species decreasing (Schmitt et al., 2024). The plant species along forest roads could serve as nectar sources, breeding place (Munguira & Thomas, 1992), or larval hostplants for butterflies (Dennis, 2010). The complexity of vegetation structure, such as species composition, number of species, height of plants, and abundance of floral resources, can positively affect butterfly populations (Han et al., 2022). In particular, the nectariferous flowers' abundance could be one of the key factors influencing the diversity of butterflies along the forest roadsides (Barberis et al., 2025).

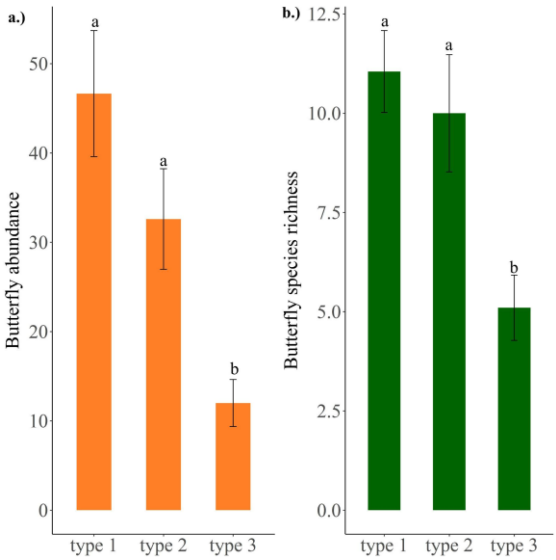
In this study, the potential of forest road verges as a nectar resource habitat for butterflies was explored. The relationship between flowering plant species diversity and adult butterfly diversity was assessed along forest road verges of varying widths.

Materials and Methods

The study was carried out at two forest areas in Latvia – in the central part (Jelgava) and central-eastern part (Kalsnava) of the country. The surrounding landscape was predominantly composed of production forests dominated by Scots pine (*'Pinus sylvestris'*), Norway spruce (*'Picea abies'*) and birch (*'Betula sp.'*). In total, 25 km of roads were selected to represent three distinct verge types: verges wider than 5 m (totaling 10 km), verges narrower than 5 m (totaling 5 km), and vegetation-covered roads without managed roadsides (totaling 10 km). The studied managed road verges were mowed once yearly. The active sampling line-transect method was used to survey butterflies in the summer of 2024 and 2025. Each kilometer of selected forest road was represented by two 200 m transects located along both sides of the road. In total, butterflies were observed along 50 transects. Butterflies were studied at each studied area five times in 2024 and four times in 2025, once during the following periods: 17 – 20 May, 30 May – 1 June, 16 June, 28 June, 16 July in 2024 and 30 May, 15 June, 2 July, 17 July in 2025. All individuals within a range of 2.5 m on both sides and 5 m in the front were recorded (Pollard & Yates, 1993) during the slow walk along the transects. Butterflies that could not be identified instantly or from a distance were captured using a butterfly net and released following identification (Tolman & Lewington, 2008). Butterflies were noted during days with no precipitation and temperatures above 17 ºC and wind below 10 m s^{-1}. The nomenclature of butterfly species followed Arvik et al. (2017, 2021, 2025). Flowering plant species diversity was counted using the transect-plot method. In total, one butterfly transect was characterized by three vegetation transects (10×2 m) located perpendicular to the road axis at the beginning, middle, and end of the butterfly transect. All flowering

plant species and their relative cover were recorded in 20 squares (1×1 m) within one transect three times per summer. In total, 180 vegetation plots described one butterfly transect. Butterfly abundance (total number of individuals) and species richness (total number of species) were calculated for each transect as the sum of records across all surveys. Flowering plant cover and richness were estimated for the same transects as the total flowering plant cover and number of species recorded across all vegetation plots in three surveys.

The effects of road type (categorical predictor) and flowering plant cover on butterfly species richness and abundance were analyzed using generalized linear models with a negative binomial error distribution (nbGLM) due to overdispersion in the count data. The study site was included as an additional categorical predictor in each model to account for site-level differences. Flowering plant richness among road types was also tested using nbGLMs, while variation in flowering plant cover was analyzed using a linear model (LM). The significance of models was assessed using analysis of variance (ANOVA). When significant effects of the categorical predictor (road type) were detected, pairwise comparisons of estimated marginal means were performed using Tukey-adjusted p-values. All analyses were performed in R version 4.4.3 (R Core Team, 2025). Negative binomial models were fitted using the MASS package (Venables & Ripley, 2002), and pairwise comparisons of estimated marginal means were obtained using the emmeans package (Lenth, 2025). A significance level of $\alpha = 0.05$ was applied.



Results and Discussion

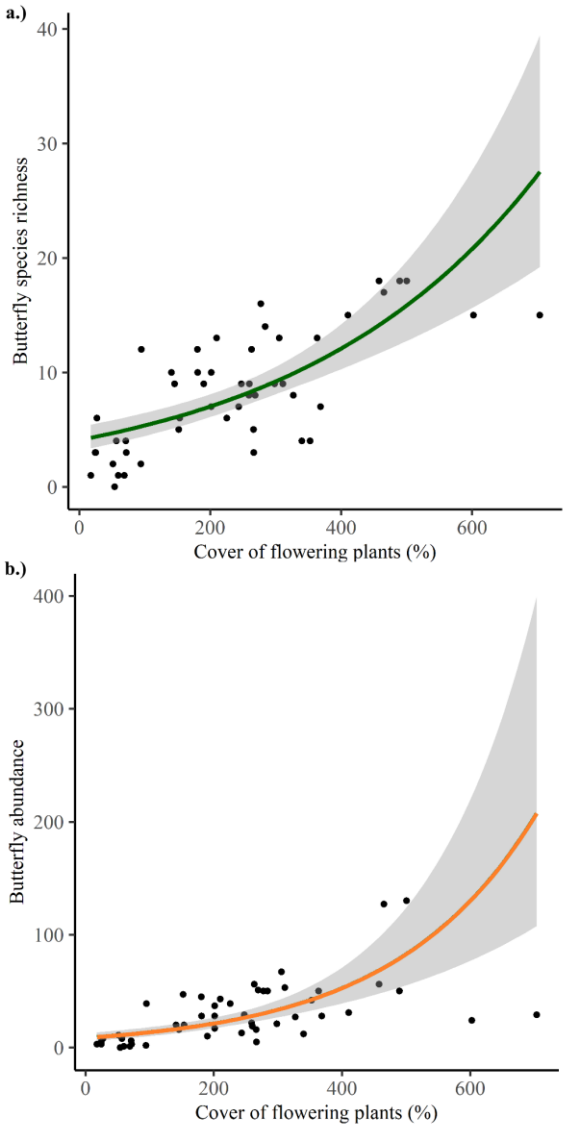
In total, 51 butterfly species were recorded along the studied road verges, the most common being *Aphantopus hyperantus, Pieris napi*, and *Argynnis paphia.* Overall, six grassland indicator species and two protected species were found (Table 1). The majority of species were recorded in less than 20% of the studied transects (Table 1).

Mean butterfly species richness per transect was the highest along roads with verges more than 5 m (11.0 ± 1.03 species), followed by roads with verges narrower than 5 m (10.0 ± 1.48), and the lowest along vegetation-covered roads without managed roadsides (5.1 ± 0.82; Figure 1b). A negative binomial generalized linear model (nbGLM) indicated a significant effect of road type on butterfly species richness (χ^2 = 23.09, p < 0.001). Mean butterfly abundance per transect showed a similar pattern, being the highest along roads with verges more than 5 m (46.6 ± 7.06 individuals), followed by roads with verges narrower than 5 m (32.6 ± 5.63), and the lowest along vegetation-covered roads (12.0 ± 2.63; Figure 1a). The nbGLM likewise indicated a significant effect of road type on butterfly abundance (χ^2 = 29.99, p < 0.001). Tukey-adjusted pairwise comparisons indicated significantly lower butterfly richness and abundance along vegetation-covered roads than along roads with managed verges (p < 0.05), while no significant differences were detected between the two managed road types (p > 0.05).

Figure 1

Mean butterfly abundance (a) and species richness (b) across three forest road types. Bars represent observed mean values ± standard errors. Type 1 - roads with verges more than 5 m; type 2 - roads with verges narrower than 5 m; type 3 - vegetation-covered roads without managed roadsides. Different lowercase letters denote significant differences among road types, as determined from estimated marginal means of nbGLM (Tukey-adjusted post hoc test, p < 0.05)

The nbGLM indicated a significant increase in butterfly species richness with increasing flowering plant cover (χ^2 = 38.58, p < 0.001; Figure 2a). Similarly, butterfly abundance increased significantly with flowering plant cover (χ^2 = 32.49, p < 0.001; Figure 2b).

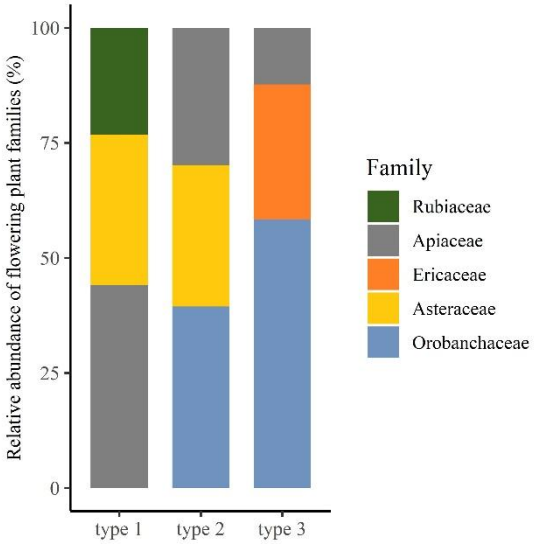


A total of 173 flowering plant taxa were recorded in the studied plots, representing 32 plant families, with the highest number of taxa in the families Asteraceae (33), Caryophyllaceae (17), and Fabaceae (13). The nbGLM indicated significant differences in flowering plant richness among road types (χ^2 = 55.5, p < 0.001), with the lowest richness along vegetation-covered roads, while no significant differences were detected between the two road types with managed verges (Tukey-adjusted comparisons; p > 0.05). Similarly, the linear model (LM) indicated that flowering plant cover differed among road types ($F_{2,46}$ = 24.5, p < 0.001) and was also the lowest along vegetation-covered roads.

In all previously described models, the study site was also included as a predictor to account for site-level differences. In the models including road type as a predictor, butterfly species richness differed significantly between the study sites (χ^2 = 5.41, p = 0.02), whereas butterfly abundance did not (χ^2 = 0.04, p = 0.85). Flowering plant richness and

cover also differed significantly not only among road types but also between study sites ($\chi^2 = 6.13$, $p = 0.013$; $F_{1,46} = 5.15$, $p = 0.028$). These differences may partly reflect the uneven distribution of road types between the two study sites, as road type 2 was absent in one site. However, in the models including flowering plant cover as a predictor, the study site had no significant effect on butterfly richness or abundance ($p > 0.05$), suggesting that differences in butterfly communities between sites were largely associated with differences in flowering plant cover.

Figure 2



Relationship between flowering plant cover and butterfly species richness (a) and abundance (b) estimated using negative binomial generalized linear models with 95% confidence intervals. Flowering plant cover (%) represents the sum of the percentage cover of flowering plants across all surveys and plots within each transect

The relative cover of dominant flowering plant families was different among road types, with roads with managed verges dominated by Apiaceae and Asteraceae, whereas vegetation-covered roads were dominated by Orobanchaceae and Ericaceae (Figure 3).

Figure 3

Mean relative abundance (%) of flowering plant families across three forest road types. Stacked bars indicate the proportional contribution of the three most abundant plant families within each road type. Type 1 - roads with verges more than 5 m; type 2 - roads with verges narrower than 5 m; type 3 - vegetation-covered roads without managed roadsides

Our study indicates that managed forest road verges may provide suitable habitat for diverse butterfly species. At our research sites, 51 out of 120 butterfly species occurring in Latvia (Aarvik et al., 2017, 2021) were recorded along the forest roads. Furthermore, considering the species composition, the road verges were able to support not only widespread grassland indicator species but also forest species as 18 of all recorded species mainly occur in the forest landscape and have host plants related to forest structures such as trees or understory plants (Viljur et al., 2020). However, we did not record any specialist species, and also the two protected species we found were widespread butterflies according to IUCN classification (Teļnovs, 2025) and have a low risk of extinction.

It has been shown that wider road verges may support higher butterfly species diversity (Meinzen et al., 2024). Although our results did not show a significant difference, there was an observed tendency to have higher richness and abundance of butterflies and of flowering plant species along roads with wider verges. The possible explanation that the width of verges did not affect species diversity significantly could be related to similar environmental conditions of adjacent forests in the studied areas (Saarinen et al., 2005). On the other hand, our results could indicate that exactly five meters is the part of the managed roadsides that

support this high diversity of flowering plants, as there were no significant differences between flowering plant richness and abundance between the two types of managed road verges.

Nevertheless, our study revealed that managed forest roadsides have a positive effect on butterfly diversity and that there is a positive interaction between flowering plant diversity and butterflies. Forest verges create open canopy conditions which increase structural complexity and floral species diversity due to better light conditions, thus promoting a more favourable environment for flowering plant species, including nectariferous flowers (Muscolo et al., 2014). Consequently, the positive association between nectariferous flowers' abundance explains a greater increase in butterfly richness and abundance (Ohwaki et al., 2017). However, not only the abundance of flowering plants but also their composition is an important aspect, because plant-pollinator interactions depend on nectar sugar composition in plant species, which differs between plant orders and families (Liu et al., 2024). According to our findings, the managed road verges were represented by an abundance of such nectar plant families as Asteraceae and Apiaceae that support high butterfly richness (Denis, 2010). The plant species of these families were less common along unmanaged forest roads. Overall, the present study findings support the assumption that high nectar abundance along the forest road verges could increase the number and abundance of butterflies (Saarinen et al., 2004).

The study site significantly affected the butterfly species richness between different road types, thus indicating that species number per site is determined not only by the road corridor itself, but by the various surrounding forest characteristics. The most important of those could be forest site type and forest cover abundance adjacent to the studied roadsides (Viljur et al., 2020). In addition, the fluctuation in the number of butterflies between studied sites could also be driven by meteorological factors (Schmitt et al., 2024) as the assessment in each site was conducted in separate summers.

Overall, the results from the present study showed that road verges could be important linear structures for supporting butterfly species, especially widely common species. Furthermore, in line with other findings (Dániel-Ferreira et al., 2023; Horstmann et al., 2025), we suggest that it is important to maintain flowering plant diversity along the forest road verges to support the conservation of butterflies. However, our study mainly focused on one aspect - flowering plant species' relations to butterflies. Thus, our results should be considered in the context of other essential local and landscape factors important for butterflies (Viljur et al., 2020), for example, microclimate, forest road density, vegetation heterogeneity, and forest structural characteristics. Furthermore, there is need for more research to understand the significance of forest road verges in supporting forest and semi-natural grassland butterfly communities in managed forest landscapes.

Table 1

Occurrence (%) of recorded butterfly species across all transects (n=50). Grassland indicator species are marked with [1] (European Environment Agency, 2025), and protected species according to Regulation of Government of Latvia Nr. 396 (2000) are marked with [2]

Coenonympha pamphilus (Linnaeus, 1758)[1]	14	*Pieris brassicae* (Linnaeus, 1758)	6	*Satyrium pruni* (Linnaeus, 1758)	2

Conclusions

1. Forest roadsides may serve as habitats supporting flowering plant and butterfly species diversity, including grassland indicator and rare species.
2. The cover and richness of flowering plants positively contribute to butterfly species diversity along forest roadsides.
3. The variation of butterfly species diversity along differently managed forest road verges could be attributed to the availability of nectar plants.

STAND DENSITY EFFECTS ON GROWTH AND STEM QUALITY OF HYBRID LARCH IN LITHUANIA

***Loreta Semaškienė, Sinilga Černulienė**

Abstract
Initial planting density is a key factor influencing stand development, productivity, and stem quality in plantation forests. This study aimed to assess the effect of different initial planting densities on growth characteristics, stem quality, and sanitary condition of hybrid larch stands. The study was conducted in the Vaišvydava forest district (Lithuania) and included seven stands established under different initial densities. In total, 455 trees were measured. The analysis focused on dendrometric indicators (mean diameter, mean height, stand volume) as well as stem quality and sanitary condition parameters. Descriptive statistics were used to compare stands of different densities, and principal component analysis (PCA) was applied to integratively evaluate relationships among growth, quality, and sanitary indicators. The results revealed clear density-related differences in stand structure. Increasing initial planting density was associated with decreasing mean tree diameter, while mean height and stand volume increased, indicating stronger competition in denser stands. Low-density stands were characterized by larger diameters but poorer stem quality, including thicker branches and less straight stems. The most favourable combination of productivity and stem quality was observed in stands of intermediate density (3000–5000 trees ha^{-1}). PCA results confirmed a clear separation of stands along gradients of productivity and stem quality, highlighting the trade-off between individual tree growth and overall stand performance. The findings demonstrate that intermediate initial planting densities provide a balanced compromise between stand productivity and stem quality in hybrid larch stands, supporting their importance for sustainable plantation management.
Keywords: hybrid larch, stand density, dendrometric characteristics, productivity, principal component analysis (PCA).

Introduction

Modern forest management is increasingly oriented toward solutions that allow the reconciliation of stand productivity, wood quality, and long-term stability under changing climatic and economic conditions. In recent years, growing attention has been directed toward tree species diversification and the use of alternative, highly productive species in order to reduce risks associated with the climate sensitivity of traditional species, particularly Norway spruce (Lindner et al., 2014; Puettmann et al., 2009). In this context, European larch (*Larix decidua* Mill.) and its hybrids are considered a promising species for sustainable forest bioeconomy development (Matras & Pâques, 2008).

Recent studies indicate that European larch exhibits high growth potential and favorable wood quality under Northern and Central European conditions, especially on fertile sites and former agricultural land, where in some cases it surpasses Norway spruce in both increment and physical wood properties (Zeidler et al., 2022; Debryniuk et al., 2022). Moreover, recent research emphasizes that larch wood in more mature stands demonstrates advantageous mechanical and strength properties, which are important for evaluating economic returns and rotation length (Gil-Moreno et al., 2023).

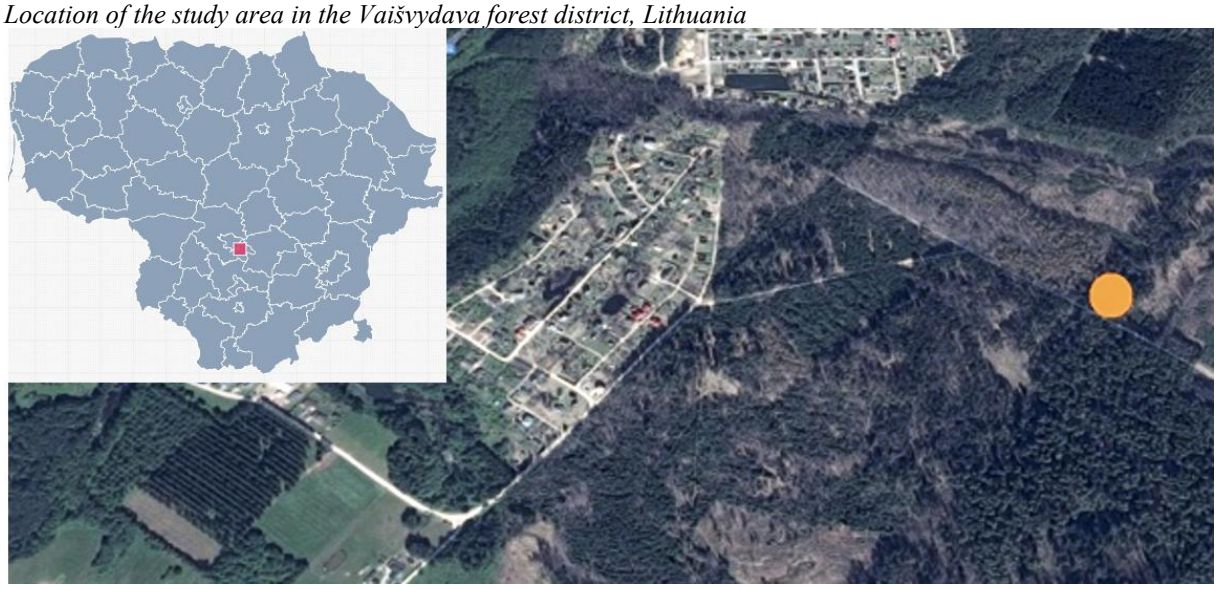
At the same time, it is emphasized that long-term development outcomes of larch stands are closely linked to early forest establishment decisions. One of the most important of these decisions is initial planting density, which determines stand structure, growth dynamics, and the formation of wood quality. It has been established that high initial density promotes the height growth and total stand volume accumulation but often restricts diameter increment and may negatively affect stem quality, whereas excessively low density creates conditions for increased branchiness and lower commercial timber value (Juodvalkis, 2004). As noted by Malinauskas (2003), these effects are particularly pronounced in larch plantations, as planting density significantly influences branch thickness, stem straightness, and the formation of merchantable logs.

Although the effects of planting density have been widely examined in young and middle-aged stands, recent studies emphasize the importance of long-term observations for assessing stand stability, sanitary condition, and the sustainability of productivity at more advanced developmental stages (Sagar et al., 2025). Long-term analyses of stands established under different initial planting densities remain limited under Baltic region conditions, particularly in hybrid larch stands, which may become an important component of forest management diversification.

Under Lithuanian conditions, larch remains a niche species; however, it is attracting increasing interest, as its productivity and stem quality potential – especially on fertile sites – may represent an important component of forest adaptation to climate change and species diversification strategies.

In this context, the aim of the present study was to assess how different initial planting densities of hybrid larch stands determine the long-term balance between stand productivity, stem quality, and sanitary stability, in order to support rational decision-making in sustainable forest management practice.

Materials and Methods



The study area is located in southern Lithuania within the Vaišvydava forest district and comprises an experimental hybrid larch plantation designed to assess

the effects of initial planting density on stand development. The location of the experimental plots is presented in Figure 1.

The plantation was established in 1983 in compartment 39 (stand 16) on a total area of 2.0 ha. The experiment consisted of six initial planting density treatments: 500; 1,000; 1,500; 2,000; 5,000 and 10,000 trees ha^{-1}. Planting spots were arranged in a square layout. The area of each density variant was 0.12 ha, except for the 5,000 and 10,000 trees ha^{-1} treatments, which covered 0.05 ha each.

Figure 1

Location of the study area in the Vaišvydava forest district, Lithuania

Field measurements were carried out during the winter of 2024–2025. In total, 455 trees were measured across all experimental plots. For each plot, dendrometric, stem quality, and sanitary condition indicators were recorded. The following indicators were measured for each tree: diameter at breast height (1.3 m), total tree height, height to dead branches, Kraft class, stem straightness, branch thickness, sanitary condition, and stand volume per hectare.

Diameter at breast height was measured using callipers, and tree height was determined using a hypsometer. Height to dead branches was measured using a measuring tape.

Kraft class was determined according to a five-class system, where 1 indicates dominant trees and 5 indicates dead or strongly suppressed trees. Kraft class values presented in the tables represent mean values calculated from individual tree classifications. Stem straightness was assessed using a five-point scale, where 1 indicates a very straight stem, 3 indicates moderate curvature, and 5 indicates a strongly curved stem. Branch thickness was evaluated using a five-point scale, where 1 indicates very thin branches, 3 indicates moderate thickness, and 5 indicates very thick branches. Sanitary condition was assessed visually using a five-point scale, where 1 indicates very good condition, 3 indicates moderate condition, and 5 indicates very poor condition.

Stand volume (m^3 ha^{-1}) was calculated based on standard volume equations using tree diameter and height.

All collected data were compiled and processed using Microsoft Excel and the R statistical environment. Descriptive statistics (mean ± standard deviation) were calculated to compare growth and quality characteristics among stands with different initial planting densities. To integratively evaluate relationships between growth parameters, stem quality indicators, and sanitary condition in relation to initial density, principal component analysis (PCA) was applied. Statistical analyses were performed using R software with base functions. Prior to PCA, all variables were standardized, and interpretation was based on the loadings and scores of the first two principal components.

Results and Discussion

Pronounced differences in dendrometric characteristics and stem quality were identified among hybrid larch stands established at different initial planting densities. With increasing initial stand density, mean tree diameter decreased, while mean tree height and total stand volume increased, indicating intensified inter-tree competition in denser stands. Mean values of tree diameter, height, and stand volume across different initial planting densities are presented in Table 1. The largest mean diameters were recorded in low-density stands (500–1,500 trees ha^{-1}), where mean diameter ranged from 29.1 to 31.1 cm. As stand density increased to 3,000–10,000 trees ha^{-1}, mean diameter decreased to 26.5–26.8 cm. In contrast, mean tree height and stand volume increased with increasing density, with the highest heights (25.2–25.65 m) and stand volumes (466–536 m^3 ha^{-1}) observed in the densest stands.

The effects of initial planting density on stem quality and sanitary condition indicators are presented in Table 2. In the lowest-density stands (500–1,000 trees ha^{-1}), higher branch thickness scores and poorer stem straightness were recorded. Stands of intermediate density (3,000–5,000 trees ha^{-1}) exhibited more favourable stem formation characteristics, including thinner branches, improved stem straightness, and better sanitary condition. In stands with very high density (10,000 trees ha^{-1}), some quality indicators remained good; however, they were not consistently superior to those observed in stands of intermediate density.

Table 1

Dendrometric characteristics of hybrid larch stands under different initial planting densities

Initial density, trees ha^{-1}	Mean diameter, cm	Mean height, m	Stand volume, m^3 ha^{-1}
500	29.5±3.2	23.20±1.1	280±40
1,000	29.1±3.0	23.20±1.0	422±55
1,500	31.1±3.5	23.10±1.2	409±50
2,000	27.2±2.8	23.35±1.1	390±45
3,000	26.8±2.6	24.10±1.3	464±60
5,000	26.6±2.5	25.65±1.5	466±65
10,000	26.5±2.4	25.20±1.4	536±70

Table 2

Stem quality and sanitary condition indicators of hybrid larch stands under different initial planting densities

Initial density, trees ha^{-1}	Kraft class	Branch thickness score	Height to dead branches, m	Stem straightness score	Sanitary condition score
500	2.2	3.3	2.0	2.5	1.4
1,000	2.1	3.1	1.8	2.0	1.1
1,500	2.2	3.5	1.1	2.1	1.2
2,000	2.4	3.1	2.2	1.9	1.2
3,000	2.2	2.9	1.1	1.8	1.0
5,000	2.0	2.9	2.5	1.6	1.0
10,000	2.2	3.2	1.8	1.7	1.1

The relationships identified between initial planting density, tree diameter, height, and stand volume are consistent with general density-related patterns reported in studies of plantation and coniferous stands. Previous research indicates that increasing stand density intensifies competition for light and promotes height growth and total biomass accumulation, while simultaneously limiting radial growth and increasing the risk of unfavourable stem formation (Tymińska-Czabańska et al., 2022; Li et al., 2025).

In stands of intermediate density, improved commercial stem structure was observed, characterised by reduced branching and more favourable stem straightness. This finding is consistent with previous studies highlighting the advantages of intermediate density levels compared with very sparse or extremely dense stands (Jiang, 2007).

Principal component analysis (PCA) was applied to integratively assess growth, stem quality, and sanitary condition indicators in hybrid larch stands established at different initial planting densities. The results showed that the first principal component (PC1) explained 65.7% of the total variance, while the second component (PC2) accounted for 19.5%, with the first two components together explaining 85.2% of the overall data structure. This level of explained variance indicates that PCA is an appropriate and informative method for interpreting the effects of planting density on stand structure and productivity.

The PCA loading analysis revealed that the first principal component (PC1) was primarily influenced by stand volume and mean tree height, whereas mean diameter and branch thickness loaded in the opposite direction. The second principal component (PC2) was mainly associated with height to dead branches and sanitary condition, reflecting stem quality and structural characteristics (Table 3).

The PCA biplot clearly demonstrated the separation of hybrid larch stands with different initial planting densities according to productivity and structural characteristics (Figure 2). This structure reflects a gradient from low-density stands, characterised by more intensive radial growth and increased branching, to high-density stands, which exhibit enhanced height growth and greater total stand volume. Similar relationships between stand density and productivity have been reported in other coniferous and plantation forests, where increasing density intensifies competition for light and promotes height growth and biomass accumulation (Thurm & Pretzsch, 2021).

The second principal component (PC2) mainly reflected stem quality and sanitary condition attributes. The positive direction of PC2 was associated with a greater height to dead branches and better sanitary condition, whereas the negative direction was related to increased branch thickness and poorer stem structural characteristics.

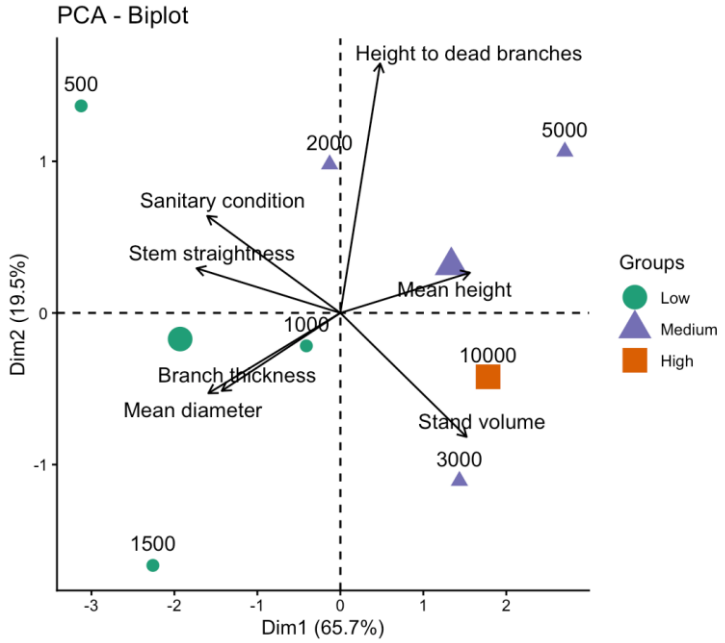


Table 3

Loadings of variables on the first two principal components (PC1 and PC2)

Variable	PC1	PC2
Mean diameter	-0.86	-0.32
Branch thickness	-0.82	-0.41
Stem straightness	-0.55	0.48
Sanitary condition	-0.49	0.62
Mean height	0.61	0.18
Stand volume	0.79	-0.36
Height to dead branches	0.12	0.87

Figure 2

Principal component analysis (PCA) biplot of hybrid larch stands based on growth, stem quality and sanitary indicators. The first principal component (PC1) explains 65.7% of the total variance, while the second component (PC2) explains 19.5%

In the PCA space, extreme initial density variants were clearly distinguished. Low-density stands (500–1,000 trees ha^{-1}) were associated with larger mean tree diameters and thicker branches but exhibited poorer stem straightness and sanitary condition. This is consistent with findings reported by other authors, indicating that excessively low initial stand density, although promoting individual tree growth, often results in inferior commercial timber structure and a higher occurrence of defects (Li et al., 2024). In contrast, very high-density stands (10,000 trees ha^{-1}) were positioned closer to the productivity axis in the PCA space; however, their location suggests that high stand volume does not necessarily ensure optimal stem quality.

Stands with intermediate initial densities (3,000–5,000 trees ha^{-1}) occupied an intermediate position between the productivity and stem quality axes in the PCA biplot, reflecting a more balanced relationship between growth and structural attributes. Such a balance between productivity and structural heterogeneity is widely discussed in the literature and is considered one of the key challenges in long-term forest stand management (Zeller et al., 2021).

The obtained PCA results are also consistent with studies on larch growth conducted in other regions, where interactions between stand density and age significantly influence growth trajectories and structural characteristics at more advanced developmental stages (Tian et al., 2023). This indicates that the patterns identified in the present study are neither local nor incidental but reflect general mechanisms governing the development of hybrid larch stands.

Conclusions

1. The effect of initial planting density on the development of hybrid larch stands was clearly expressed in both growth and stem structural indicators. With increasing initial density, mean tree diameter decreased, while tree height and total stand volume increased, reflecting intensified inter-tree competition in denser stands.

2. Stands established at low initial planting densities exhibited larger individual tree diameters; however, poorer stem quality indicators were also recorded, particularly increased branching and reduced stem straightness, which limit the formation of merchantable timber. In contrast, stands with a very high initial density achieved the highest stand volume, although this volume was not consistently associated with optimal stem quality.
3. Stands with intermediate initial planting densities were characterised by a balanced relationship between growth and structural attributes, combining sufficiently high stand productivity with more favourable stem quality and sanitary condition indicators. This suggests that intermediate initial density provides the most favourable conditions for the formation of hybrid larch stands.
4. Principal component analysis further confirmed that the effect of initial planting density on stand development is expressed through a clear gradient between productivity and stem quality, allowing intermediate density to be identified as an optimal balance between stand volume and stem structural characteristics.

INDOOR SEED PRODUCTION OF SILVER BIRCH (*BETULA PENDULA* ROTH): CURRENT KNOWLEDGE AND RESEARCH NEEDS

***Aldis Sproģis[1], Alise Bleive[2], Kaspars Liepiņš[1,2]**
[1]Latvia University of Life Sciences and Technologies, Jelgava

Abstract
Silver birch is the most economically important deciduous tree species in the Nordic and Baltic countries and represents a key raw material for the rapidly expanding plywood and wood-based panel industries. Although birch, as a pioneer species, primarily regenerates naturally, the use of genetically improved reproductive material can substantially increase stand productivity and improve stem quality. Reliable production of genetically superior seed is therefore a critical prerequisite for sustainable birch forestry. A technology for intensive birch seed production in plastic-covered seed orchards, originally developed in Finland, has been adopted across Northern Europe, enabling seed production within only a few years after orchard establishment. However, operational experience in Latvia and other countries indicates large variation in seed yield, regularity, and quality between years and orchards. These inconsistencies are largely driven by poorly understood interactions between orchard microclimate, genetic background (clone composition), and reproductive phenology, as well as by limitations in pollination processes under controlled environments. This narrative review synthesizes current knowledge on birch seed production in plastic-covered orchards with a specific focus on Nordic and Baltic conditions. We summarize existing management practices, experimental findings, and ongoing research efforts, and identify critical knowledge gaps related to flowering induction, pollination efficiency, microclimate regulation, and clonal selection. The review defines priority research directions required to achieve earlier, more regular, and higher seed yields, and provides a scientific basis for improving seed supply systems supporting large-scale forest regeneration under changing climatic conditions.
Keywords: reproductive phenology, forest tree breeding, seed orchards, seed yield stability, flowering induction.

Introduction

Forests provide a wide array of ecosystem services that are essential for human well-being and sustainable economic development, including the provisioning of timber as a key resource for the bioeconomy and long-lived wood products. In Europe, boreal and temperate forests not only contribute to climate regulation, water purification, and biodiversity conservation, but also underpin regional industrial sectors such as wood-based panel and plywood manufacturing (European Environment Agency, 2023, 2024; Eurostat, 2026). The strategic importance of forest ecosystems is reflected in national and international policies recognising forests as multifunctional landscapes that supply both ecological and socio-economic benefits (Ministry of Agriculture of the Republic of Latvia, 2018).

Improving forest productivity and adaptive capacity under changing climatic conditions has become a central objective of forestry research and practice. Historically, tree breeding and genetic improvement efforts have focused on enhancing growth, wood quality and vitality, particularly in conifer species such as Norway spruce (*Picea abies*) and Scots pine (*Pinus sylvestris*) in the Northern European context (Danell, 1991; Egbäck et al., 2018). However, there has been an increasing emphasis on broadening breeding goals to include genetic diversity and resilience to environmental change, reflecting the need to support ecosystem health and long-term sustainability under global change pressures (Li et al., 2025).

Within this broader framework, deciduous tree species have received growing attention in breeding and forest management programmes (Gailis, 2026; Liziniewicz et al., 2022; Rosvald, 2011). Among these, silver birch (*Betula* pendula Roth) and downy birch (*Betula pubescens* Ehrh.) are ecologically and economically significant across the Baltic Sea region (Hynynen et al., 2009). Birches occur widely in boreal and temperate forests, contribute to biodiversity and soil functioning, and play a role in early successional dynamics, while their wood is highly desired in plywood production and bio-based material value chains (Cakiroglu et al., 2019; Dubois et al., 2020; Jonczak et al., 2020).

The heightened demand for high-quality birch timber, driven by both domestic industry and bio-refining innovation, has stimulated interest in advancing reproductive and silvicultural systems that can deliver improved seed supply. Additionally, ensuring sustainable domestic supply chains is of strategic importance in many countries, as disruptions caused by global geopolitical and trade uncertainties underscore the vulnerability of imported reproductive material and wood resources.

Compared with conifer species, breeding cycles in birch can be completed substantially faster due to its earlier onset of flowering and shorter generation intervals, allowing more rapid genetic gain (Hynynen et al., 2009; Koski & Rousi, 2005). In addition, the establishment of seed orchards in indoor facilities, such as plastic-covered greenhouses, enables intensive management and has been shown to result in abundant seed yields already a few years after orchard establishment (Ahtikoski, 2000; Lepisto, 1973).

Plastic-covered greenhouse seed orchards enable high genetic control and regulated seed production through pollen isolation and controlled environments, their high costs, technical complexity, limited integration with field forestry, and potential risks related to seed quantity, viability and clonal balance represent important constraints (Wilson, 2015).

Indoor birch seed orchards were first developed in

Finland in early seventies of last century, where this technology was introduced to accelerate seed production and improve genetic control, and it has since been adopted in several countries like Sweden, Baltic countries, Iceland, Germany and China (Poykko, 2007). Although general management principles for birch seed orchards have been described by Finnish specialists (Poykko, 2013), the physiological thresholds and reproductive conditions underpinning regular and abundant seed production remain insufficiently defined.

Despite decades long use of plastic-covered greenhouse seed orchards and the availability of general management guidelines, practical experience demonstrates that seed production in birch orchards often remains irregular (Isio, 2024). Substantial inter-annual variation is frequently observed not only in seed yield but also in seed quality parameters, such as viability and germination capacity. These fluctuations indicate that the biological regulation of flowering, pollination success and seed development under controlled greenhouse conditions is still incompletely understood. In particular, the relative roles of internal physiological factors and external environmental conditions in driving year-to-year variation in reproductive output have received limited empirical attention.

This knowledge gap constrains the optimisation of intensive birch seed production systems and limits the predictability and reliability of genetically improved seed supply, which is increasingly critical for both breeding programmes and forest regeneration strategies.

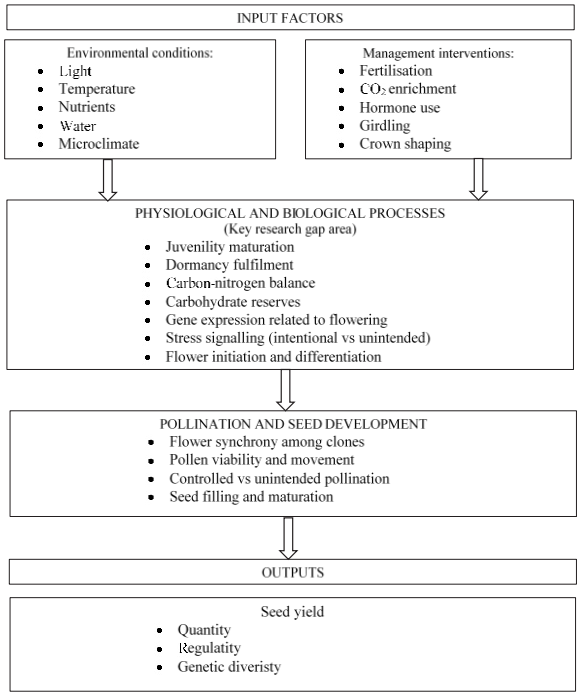
The aim of this review is to synthesise existing knowledge on birch seed production in plastic-covered greenhouse seed orchards and to identify key research gaps limiting the predictability, regularity and quality of seed yields. By evaluation of current management approaches, biological processes and environmental controls described in the literature, this review seeks to define priority directions for future research needed to optimise intensive birch seed production systems and support reliable supply of genetically improved reproductive material for forest regeneration.

Materials and Methods

Literature search

This review is based on a comprehensive survey of peer-reviewed scientific literature focusing on Silver birch (*Betula pendula* Roth) flowering, seed production and the management of plastic-covered greenhouse seed orchards. Literature searches were conducted primarily using the bibliographic databases Scopus and Web of Science, which were selected due to their broad coverage of forestry, plant physiology and applied silviculture research. Additional sources were identified through reference list screening of key publications and relevant monographs, conference materials and institutional reports where appropriate.

Search queries combined terms related to species, reproductive biology and seed production systems. The core search strings included, but were not limited to: ‘birch flowering’, ‘flower induction’, ‘reproductive phenology’, ‘seed orchard management’, ‘plastic-covered greenhouse’, ‘controlled environment seed production’, and ‘*Betula* seed yield’.



Search terms were applied in various combinations and adjusted iteratively to ensure comprehensive coverage of the topic.

Scope and synthesis approach

The review follows a structured narrative approach, integrating findings from experimental studies, applied seed orchard research and physiological investigations. Particular emphasis was placed on identifying consistencies and discrepancies among studies, as well as areas where empirical evidence remains limited or fragmented. In total, 58 literature sources were systematically reviewed and synthesised in this study.

Figure 1

Interactions among environmental conditions, management interventions and genetic factors influencing flowering initiation and seed crop in plastic-covered birch seed orchards

Conceptual framework

To support synthesis and interpretation, this review proposes the development of a conceptual framework illustrating the principal biological, environmental and management-related factors influencing seed yield and quality in plastic-covered birch seed orchards. Such a schematic representation is intended to clarify interactions among flowering induction, pollination processes, clonal effects and controlled environmental conditions, and to assist in identifying priority directions for future research.

Figure 1 synthesises the key environmental, management

and genetic factors influencing reproductive processes in plastic-covered birch seed orchards. Environmental conditions (light, temperature, nutrients and water regime) interact with silvicultural interventions such as fertilisation, CO_2 enrichment, crown management and controlled stress treatments, while clonal genetic characteristics determine inherent flowering capacity and phenological patterns.

These inputs act through underlying physiological processes, including maturation status, dormancy fulfilment, carbohydrate dynamics and gene activity related to flowering induction, which ultimately regulate pollination success, seed development and reproductive allocation. The resulting outputs are expressed as seed yield, yield stability and seed quality. Regulatory requirements concerning genetic diversity and reproductive material zoning operate across all levels of the system. The framework highlights the central role of physiological mechanisms as a key area where further research is needed to improve the predictability and efficiency of intensive birch seed production systems.

Results and Discussion

Reproductive cycle of silver birch

Silver birch is a monoecious, wind-pollinated tree species whose reproductive ecology is well documented. The initiation of reproductive primordia takes place during the preceding growing season, typically in mid- to late summer, when male and female inflorescences are differentiated within axillary buds on current-year shoots. Male catkins develop earlier and overwinter as externally visible structures, whereas female inflorescences remain enclosed within buds (Sarvas, 1952; Vakkari, 2009). Following winter dormancy, flowering occurs in early spring, often shortly before or concurrently with leaf flushing, with pollen release from male catkins and subsequent wind-mediated pollination of receptive female flowers (Atkinson, 1992; Hynynen et al., 2010).

Successful pollination, fertilisation and seed development depend on synchrony between pollen shedding and female receptivity, favourable spring weather conditions and adequate physiological status of the trees. Seed development proceeds throughout the summer, with maturation and dispersal occurring in late summer to early autumn. This reproductive strategy results in pronounced inter-annual variability in seed yield, as reproductive success is influenced by environmental conditions during both the year of floral initiation and the subsequent flowering and seed development phases (Hynynen et al., 2010; Pelham et al., 1984; Sarvas, 1956). Birch typically produces some seed annually, while abundant seed crops often occur at intervals of approximately two to three years (Cameron, 1996; Holm, 1994).

Genetic diversity and reproductive synchrony in seed orchards

The conservation of genetic diversity is a key consideration in the design and management of forest tree breeding and seed production systems (Ivetić et al., 2016). In seed orchards established for the production of forest reproductive material, it is essential to ensure adequate representation of selected genotypes and effective cross-pollination among them. Consequently, seed orchards typically include multiple superior clones selected for desirable traits such as growth performance, vitality and stem quality. For these orchards to function as intended breeding populations, however, it is crucial that the participating clones contribute to gene exchange through successful flowering and pollination (Eriksson et al., 2013; Lindgren & Prescher, 2005).

Even when several dozen clones are represented within a seed orchard, effective cross-pollination may remain limited if flowering intensity is low or uneven among clones. Differences in reproductive characteristics including the age at first flowering, flowering intensity and the temporal pattern of reproductive development are known to have a strong genetic component in many forest tree species (Kang, 2003; Owens & Blake, 1985). In addition, the phenology of flowering may vary substantially among clones. In wind-pollinated species such as birch, the flowering period of individual trees may be very short, sometimes lasting only a few days, meaning that asynchronous flowering among clones can significantly reduce opportunities for cross-fertilization and lead to unequal parental contributions to the seed crop (Sarvas, 1952).

Plastic-covered seed orchards offer important advantages for controlling pollination processes. The physical barrier created by the plastic covering can effectively reduce contamination from external pollen sources, while the warmer microclimate often accelerates reproductive development and leads to earlier flowering compared with natural stands. These conditions may substantially increase the genetic value of the produced seed by ensuring that pollination occurs primarily among the selected orchard clones (Harju & Nikkanen, 1996; Ruotsalainen, 2014). However, such controlled systems also place greater responsibility on orchard design and management to maintain adequate genetic diversity and balanced parental contributions over time.

For this reason, the selection of clones for seed orchard establishment should consider not only breeding traits such as productivity and quality but also reproductive characteristics, including flowering capacity and phenological compatibility.

Juvenile phase and reproductive maturity in birch

One of the key biological advantages of birch in forest reproductive material production is its relatively short juvenile phase compared with many economically important conifer species. In natural stands, silver birch typically begins producing flowers and viable seeds at approximately 10–15 years of age (Perala & Alm, 1990). This contrasts with species such as Norway spruce and Scots pine, where the onset of regular seed production often occurs several decades after stand establishment. The relatively early onset of

seed production in birch therefore represents an important advantage for breeding programmes and seed orchard establishment, enabling shorter breeding cycles and earlier availability of genetically improved reproductive material.

The transition from the juvenile vegetative phase to the generative phase represents a critical developmental threshold in woody plants. During the juvenile stage, trees are physiologically incapable of forming reproductive structures regardless of environmental conditions (Zimmerman, 1972). Only after this phase has been completed do trees acquire reproductive competence and become capable of initiating floral buds (Hackett & Murray, 1993).

Shortening the juvenile phase through the induction of early flowering has been identified as an important objective in the breeding of woody perennials (Khan et al., 2025). Experimental studies indicate that flowering in birch can occur at a very early developmental stage: under controlled conditions, reproductive structures have been observed in individuals as young as 8–30 months after germination (Longman, 1976; Longman & Wareing, 1959).These observations suggest that reproductive competence may develop early in the ontogeny of birch, although under natural conditions flowering usually occurs later, once sufficient crown development and resource accumulation have been achieved.

Understanding the factors that regulate the transition from vegetative growth to reproductive development is therefore essential for improving the efficiency of birch seed production systems.

Environmental and physiological triggers of flowering

The transition from vegetative growth to reproductive development in woody plants is controlled by a complex interplay of environmental cues and internal physiological signals (Khan et al., 2025; Wang et al., 2024). In temperate tree species, floral initiation is typically regulated by seasonal changes in environmental conditions, including photoperiod, temperature and resource availability, which interact with endogenous developmental processes to determine the timing and intensity of flowering (Wilkie et al., 2008). In birch, reproductive buds are generally initiated during the previous growing season (Dahl & Strandhede, 1996), indicating that environmental conditions experienced during summer may play a crucial role in determining the following year's flowering intensity and seed crop.

Light availability and temperature are among the most important environmental factors influencing flowering in trees. Long photoperiods and favourable temperature conditions during the growing season can promote the formation of reproductive buds (Almqvist, 2018; Tooke & Battey, 2010).

Carbon availability and the carbon–nitrogen (C:N) balance are widely considered important physiological factors influencing the initiation of flowering in woody plants. Classical plant physiology concepts suggest that relatively high carbon availability, or a higher C:N ratio, tends to favour reproductive development, whereas high nitrogen availability typically promotes vegetative growth. Early studies on woody plant development noted that the accumulation of carbohydrates in shoots and buds often coincides with periods of floral bud initiation (Kozlowski & Pallardy, 1997; Zimmerman, 1972). In forest trees, stored carbohydrates provide both energy and structural carbon for the formation of reproductive organs, and several studies indicate that greater carbon reserves may contribute to increased flowering intensity in subsequent seasons (Hoch, 2005).

Hormonal and genetic regulation of floral initiation

The transition to flowering in woody plants is regulated by complex genetic networks integrating environmental signals and internal physiological status. Among the genes associated with floral induction in birch, particular attention has been given to the MADS-box transcription factor BpMADS4, which is homologous to floral identity genes involved in the regulation of reproductive development in many angiosperms. Experimental overexpression of BpMADS4 in silver birch has been shown to induce precocious flowering, with transgenic trees producing inflorescences within the first year of growth (Elo et al., 2007; Lemmetyinen et al., 2004).

In addition to genetic regulation, plant hormones are widely known to influence floral initiation in woody perennials. Applications of gibberellins, cytokinins, or other growth regulators have been successfully used to stimulate flowering in several forest tree species, particularly conifers such as *Picea* and *Pinus* in seed orchard management (Owens & Blake, 1985; Pharis & King, 1985). However, comparable experimental evidence for effective hormone-induced flowering in birch is limited.

Stress-induced flowering responses

Stress-related physiological responses are known to influence the transition from vegetative to reproductive development in many woody plants. Numerous studies demonstrate that abiotic and biotic stressors can modulate hormonal signalling networks regulating floral induction, including changes in gibberellins, cytokinins, auxins and abscisic acid, which affect meristem identity and the initiation of floral buds (Li et al., 2024; Sun et al., 2022). Moderate stress often reduces vegetative vigour, thereby altering internal resource allocation in ways that favour reproductive development. Such conditions are frequently associated with increased carbohydrate accumulation in buds and shoots, shifts in the carbon–nitrogen balance, and changes in assimilate partitioning, all of which are recognised as important physiological cues for floral initiation in woody perennials (Song et al., 2024; Sun et al., 2022).

Stress-inducing silvicultural practices that simulate drought or disrupt vascular transport such as stem or branch girdling are widely used to manipulate reproductive development in conifer seed orchards

(Wheeler et al., 1985). Experimental studies on silver birch have shown that partial root excision and soil-drying treatments significantly alter stomatal conductance, root-to-shoot signalling and carbon allocation patterns, creating physiological conditions associated with moderate stress (Fort et al., 1998). Although these studies primarily examined physiological responses to water stress, they suggest that stress-induced changes in resource allocation and hormonal signalling may potentially influence reproductive activity in birch grown under controlled seed orchard conditions.

Future research directions for improving flowering and seed production in birch seed orchards

Despite considerable knowledge about the reproductive biology of silver birch, several important aspects of flowering regulation and seed production remain insufficiently understood. Context of intensive existing studies provide valuable insights into the ecological, physiological and molecular mechanisms underlying flowering in woody plants, however, the integration of these processes into practical seed production systems remains limited. This is especially relevant for plastic-covered seed orchards, where environmental conditions, pollination dynamics and tree physiology differ substantially from those in natural stands.

Identifying the physiological thresholds that trigger reproductive bud formation in birch is a critical research need. Although environmental cues such as photoperiod, temperature and resource availability are known to influence flowering, the specific combinations of factors required to consistently initiate floral development remain poorly defined. In particular, further research is needed to clarify the role of carbohydrate reserves, carbon–nitrogen balance and tree nutritional status in regulating flowering intensity under orchard conditions.

Another important research direction relates to the synchronisation of flowering among clones in seed orchards. Genetic variation in flowering phenology and reproductive capacity can lead to unequal parental contributions to the seed crop, potentially reducing the effective population size and genetic diversity of the produced reproductive material. Future studies should therefore investigate the extent of clonal variation in flowering timing and intensity in birch seed orchards.

Further research is also needed to evaluate the effectiveness of stress-based management practices for stimulating flowering in birch. While techniques such as drought stress, root pruning or girdling have been widely used to enhance reproductive activity in conifer seed orchards, comparable experimental studies in birch remain scarce. Investigating how controlled stress treatments influence hormonal signalling, resource allocation and floral induction in birch could provide valuable tools for improving reproductive performance in intensive seed production systems.

Overall, advancing knowledge in these areas will be essential for developing more reliable and efficient birch seed production systems capable of supporting forest regeneration and tree breeding programmes under changing environmental and socio-economic conditions.

Conclusions

1. Silver birch possesses several biological characteristics that make it particularly suitable for intensive seed production systems, including early reproductive maturity and relatively short breeding cycles compared with many economically important conifer species. The initiation of flowering in birch is controlled by a complex interaction of developmental stage, environmental conditions and internal physiological processes, including carbon balance, hormonal regulation and genetic control mechanisms.
2. Plastic-covered seed orchards provide important opportunities to improve the genetic quality and reliability of birch seed production by enabling control of pollination and orchard microclimate. However, several key knowledge gaps remain. In particular, further research is required to determine the physiological thresholds that trigger floral initiation in birch, to understand the genetic and phenological variation in flowering among clones and its impact on reproductive synchrony, and to evaluate the potential of stress-based management practices to stimulate flowering under controlled orchard conditions.
3. Addressing these research gaps will be essential for developing management strategies that ensure both regular seed production and balanced genetic contributions among clones, thereby maintaining the genetic diversity and long-term sustainability of birch seed orchard systems.

Abstract
Afforestation of low-value agricultural lands is one of the most important actions to ensure climate neutrality. There are several alternatives, one of which is short rotation cycle forests, aimed at maximizing timber production. The research aims to characterize changes in ground-cover vegetation diversity in deciduous tree plantations. The study was conducted in two black alder sites and two silver birch sites - plantation stands at a young age (12 years old). In each site, 24 sample plots of 2x1 meters were established. In each sample plot, the number of ground cover vegetation plant species, their projective cover (%), occurrence, constancy classes, and Ellenberg indicators were assessed. The average number of ground cover species (species richness) in black alder sites is 44.0, whereas in birch sites it is 35.5. The difference in the number of plant species is not statistically significant; no significant differences were observed in the average projective cover (%) of ground cover plants. Based on the study results, it is recommended to grow black alder in plantations with a greater diversity of ground-cover species. In the black alder and one silver birch plantations, no significant impact of deciduous tree species on ground cover plant diversity has been found.
Keywords: *Alnus glutinosa* (L.) Gaertn., *Betula pendula* Roth., ground cover, diversity.

Introduction

Since the 1930s, forest areas in Latvia have doubled, due to the afforestation of pastures and low-fertility arable land, as well as the urbanization process. Unused and shrub-covered agricultural land areas in Latvia are mainly located in regions with low soil fertility and a small population (Kaktiņš & Arhipova, 2005). The issue of rational and sustainable land management is topical worldwide. This issue must be addressed comprehensively by assessing the quality of the environment, economic sustainability, profitability, and social benefits. One way to manage land not used for agriculture is afforestation, which provides significant economic and ecological benefits. It limits and controls rainwater runoff and soil erosion, while reducing water, soil, organic and nutrient losses, thereby promoting the accumulation of organic matter and preservation soil biological activity. These benefits are largely determined by the proportional presence of trees in the system.

A plantation is a stand of one or two species of even age class, established with local or introduced species to obtain the maximum amount of a certain type of wood or other products in the shortest possible time. The establishment, registration, and management of plantation forests are regulated by the Forest Law (Saeima, 2000) and Cabinet of Ministers Regulation No. 308 'Regulation on Afforestation, Forest Establishment and Plantation Forests' (Ministru kabinets, 2012). The Latvian regulatory framework not only allows for the application of different management measures in these areas, but also does not exclude the possibility of returning them to agricultural production in the future (Liepiņš et al., 2013). Biomass from tree plantations is an essential component of the transition to more sustainable energy production. Increasing forest areas and establishing new plantations help limit CO_2 emissions into the atmosphere (Liepiņš, 2022). Plantation trees not only produce wood and related by-products, but also significantly improve the ecological condition of the surrounding environment. Forest plantations provide up to 33% of the total industrial roundwood used worldwide, and it is predicted that this share will reach 50% by 2040 (Liu et al., 2018).

Studies show that forest plantations, when properly managed, can preserve biodiversity by increasing the diversity of different plant and animal habitats, as well as reducing the impact of logging on commercial forests (Liu et al., 2018). Species for plantation crops should be selected not only based on the wood growth rate, but also on the suitability of the species for growth in open areas and resistance to adverse abiotic and biotic factors.

In Latvia, from 2019 to 2023, there was an upward trend in the afforestation of plantation stands. Deciduous tree species have a greater capacity to promote soil organic carbon sequestration, since they have a higher ratio of root biomass to aboveground biomass. In general, deciduous tree species have a faster growth rate and a larger, deeper root system, which, in turn, creates greater input of soil organic carbon through root litter into deeper soil layers. From the perspective of climate change mitigation, it is recommended that tree species that produce the greatest biomass in the shortest possible time will be selected for establishing forest stands. In this way, those tree species would sequester most CO_2 (Bārdulis, 2022). Black alder *Alnus glutinosa* (L.) Gaertn. is a fast-growing tree species with the largest annual growth at 20-25 years old (Mauriņš & Zvirgzds, 2009). It is a very soil-demanding species but can also grow in poor, sandy soils if oxygen-rich groundwater is nearby (Mangalis, 2004), as it is a nitrogen (N)-fixing species (Ahmed et al., 2016). Recent studies show that black alder also plays an important role in plantation forestry, since it grows well in periodically overmoist areas or in areas with high groundwater levels, forming a deep and extensive root system also in anaerobic conditions (Daugaviete et al., 2017). Silver birch,

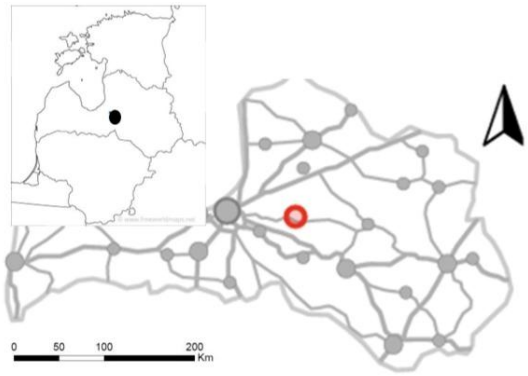
Betula pendula Roth, is a fast-growing, highly light-requiring, and highly resistant to climate extremes tree species. It grows well in well-drained, humus-rich soils. Birch has a relatively shallow but extensive root system that can reach depths of up to 2 m in loose soils. Due to its rapid growth, care for birch crops is minimal or unnecessary (Mangalis, 2004). Birch is the most commercially important deciduous tree species in Latvia. It is widely used for afforestation of agricultural lands (Liepiņš, 2011). The rapid growth characteristic of birch in its juvenile stage persists until 40-50 years of age (Daugaviete et al., 2017). Birch stands on agricultural soils are faster-growing and more productive than on forest soils, and the trees for the production of veneer logs in plantations of agricultural soils can reach the required parameters already at the age of 40 (Liepiņš, 2011). Scientists from Nordic countries consider birch a key energy tree species due to its ability to produce significant biomass in a relatively short period (15-20 years).

The ground vegetation in the forest is mainly determined by soil type and the dominant tree species, which in turn influence light intensity, its variability during the growing season, and the chemical composition of dead plant litter. Established plantations can increase plant diversity in agricultural landscapes by functioning as an additional element that provides a habitat for new species. Consequently, the resulting plant communities are highly diverse, comprising a mix of meadow, ruderal, and typical forest species. Studies have shown that plant diversity in the established plantations can be even richer than in coniferous and mixed forests (Dimitriou & Rutz, 2015). Intensive management of short-rotation timber plantations often results in soil depletion. To preserve soil fertility, it is recommended to use species that fix atmospheric nitrogen when establishing plantations, either in admixture or through species rotation. Tree species of the genus *Alnus* are characterized by symbiosis with nitrogen-fixing actinobacteria, which fix atmospheric nitrogen and deposit it in the soil in the form of nitrates available to plants. Thus, alder also increases the growth rates of other trees in the immediate vicinity (Liepiņš K. & Liepiņš J., 2010). The study aims to characterize the diversity of ground cover vegetation in deciduous tree plantations.

Materials and Methods

The research object is located in Ķeipene parish, Ogre municipality (Figure 1). The established plantation is an experimental plantation owned by the Latvian State Forest Research Institute 'Silava'. In the study, *Betula pendula* Roth and *Alnus glutinosa* (L.) Gaertn. plants planted in 2012 were selected as sample groups, with 2 plots per species. The total number of trees planted in each plot was 200. The distance between the trees was four meters. Vegetation data were collected in the summer season of 2024. A 2x1 m^2 sample plot was placed one meter away from two trees, continuing to arrange them in strips - a total of 24 sample plots in each plot (Figure 2). In each sample plot, the ground cover was characterized - the total projective cover of vegetation in %, all plant species were counted and recorded, and the projective cover of each plant species in % was determined.

Figure 1
The location of the research object



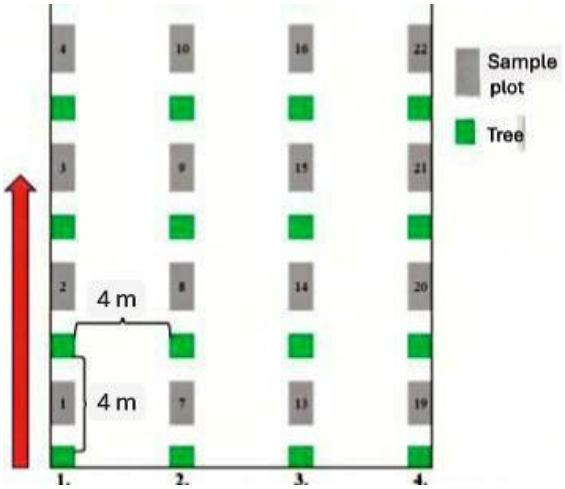


Figure 2
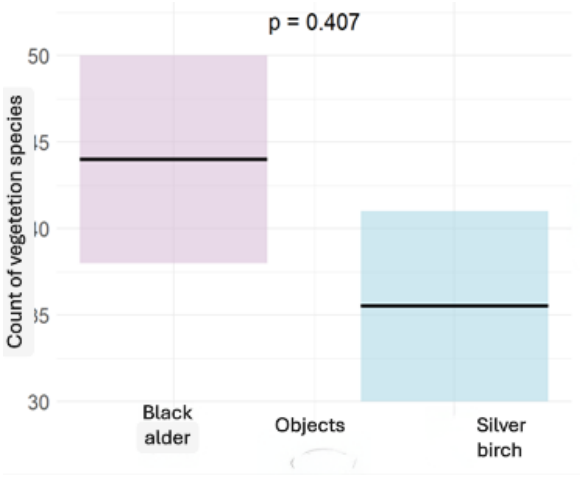
The sample plot scheme

Using Raunkiaer's formula, the occurrence coefficient was calculated for all vegetation species, which shows the frequency of occurrence of each species in the sample plots. The occurrence coefficients correspond to 5 constancy classes (percentage frequency): class I (1-20%), class II (21-40%), class III (41-60%), class IV (61-80%), and class V (81-100%). Ellenberg's ecological indicators were determined for the species of the herbaceous plant layer. They were determined for four environmental factors – moisture, light, soil reaction, and nitrogen (Ellenberg et al., 1992). Analysis of variance was performed using the ANOVA tool (Arhipova & Bāliņa, 2006).



Results and Discussion

Number of species

In *Alnus glutinosa* (L.) Gaertn. plots, 38 and 50 vascular plant species were counted and recorded,

respectively, with an average of 44 species. In *Betula pendula* Roth plots - 30 and 41 vascular plant species, respectively, with an average of 35.5 species (Figure 3). When performing an analysis of variance, it was found that the difference in the number of species across different deciduous tree plots was not statistically significant (p-value = 0.407 > 0.05).

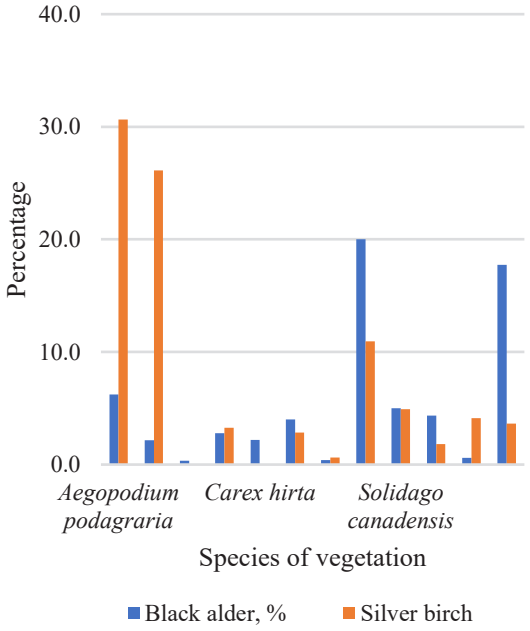


Figure 3
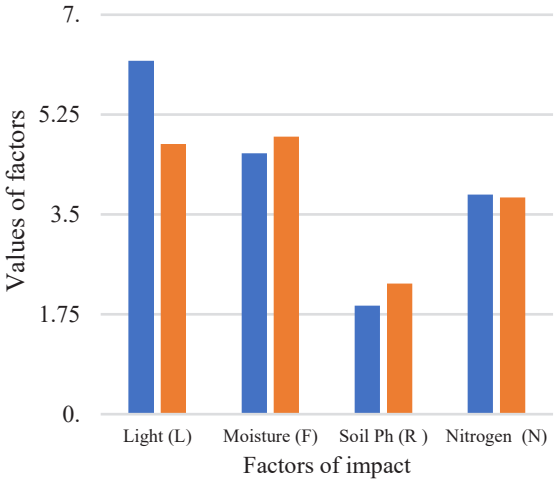
The number of plant species at each site and the average number of plant species

Species occurrence
The occurrence of a plant species indicates how often it is represented in a plant community. Plants with an occurrence of at least 50% (a plant occurs in at least two plots) and their constancy class from III-V were used for data analysis. As a result, we obtain an indicator that 31.3% of plant species from the total number of species occur in two plots - the constancy class of these plants is III (occurrence is 41-60%); 23.9% of plants are found in three plots and their constancy class is IV (occurrence 61-80%), but plants that are found in all plots (in all sample plots) are 19.4% from the total number of plants, respectively, form constancy class V (occurrence 81-100%).

Average projective cover of plants (%)
In *Alnus glutinosa* plots, the largest projective cover in a single plot is occupied by Aegopodium podagraria, indicating nitrogen-rich soil, *Veronica chamaedrys,* and *Poa sp*. In contrast, in the other *Alnus glutinosa* plot, the largest average projective cover is *Poa sp., Equisetum arvense,* and *Ranunculus repens.* In *Betula pendula* plots, the ground cover vegetation is predominantly composed of *Aegopodium podagraria*, with an average cover of 30% and 17%, respectively, as well as *Poa sp.* and *Dactylis glomerata*. In all results of the analysis of variance, the calculated p-value is >0.05, indicating that there are no significant differences in the average projective cover of ground cover vegetation across plots. Fertile soils, additional levels of plant-available nutrients lead to the increased development of aggressive herbs with high competitive ability – such as *Aegopodium podagraria*, which inhibit the immigration of woodland herbs (Orczewska, 2009). A study on the influence of tree species on the diversity and conservation of ground cover vegetation in Germany indicates that the correct choice of tree species is a practical tool to increase biodiversity in the ground cover, thus contributing to the conservation of endangered and rare species (Oijen et al., 2005) (Figure 4).

Figure 4
The comparison of the average percentage cover of the most important species



Assessing the Ellenberg ecological indicator values
Species with similar ecological factor values can be included in a single ecological group. Ecological groups provide information about environmental conditions that affect the entire plant community. The simplest way to use the indicator values of all representatives of the plant community is to calculate average factor values, which assess the relative importance of various environmental factors. According to the Ellenberg scale evaluation, the corresponding value for the specific influencing factor was found for each plant. The conditions evaluated were the following: light (L), moisture (F), soil pH (R), nitrogen (N), or nutrient concentration. Based on the numerical values of the Ellenberg scale for each plant, average values were calculated for each influencing factor in each plot (Figure 5).
The development of ground cover is not only driven by the combined influence of edaphic and light conditions, but also by the availability of water. Most woodland herbs avoid habitats with extreme hydrological conditions, both too wet and too dry, but show a clear affinity for sites with a moderate level of this abiotic factor (Orczewska, 2009). When evaluating the average values of Ellenberg's influencing factors, it can be observed that the highest

light requirements are shown by the ground cover in the second *Alnus glutinosa* plot (6.39); this indicator is also very close in the second *Betula pendula* plot (6.33). The sites with lower average light values are in the first plots (6.14 and 6, respectively). It can be concluded that in all plots there are conditions of semi-light, and no statistically significant differences were found (p-value > 0.05).

Soil moisture is one of the most important environmental factors that determine the composition, structure, and functionality of vegetation in dryland ecosystems. Studies have shown that species diversity increases with greater water availability. When assessing the impact of moisture, it can be seen that the highest average indicator is in the second *Betula pendula* plot (5.21), followed by the second *Alnus glutinosa* plot (4.97). In the first plots, the average moisture factor values are 4.17 and 4.52, respectively, indicating that all plots have moderately moist soil conditions. The impact of former agricultural land-use on forest soils has become an object of growing interest because historical land-use can influence present-day soil characteristics and, through that, also the diversity patterns of forest plant species (Orczewska, 2009).

Studies have shown a significant positive relationship between vascular plant diversity and soil pH in moderately moist to moist soils. The pH response index in plots varies from 1.87 to 2.38, indicating acidic soil conditions. Plant diversity is positively related to soil pH – higher soil pH, or more alkaline soil, is associated with a greater number of plant species (Partel et al., 2004). Former arable soils have higher nutrient concentrations resulting from previous agricultural fertilization (Lutter et al., 2016). Soil acidification has been identified as one of the main risks in fast-growing tree stands or plantations (Rajapaksha, 2012). Average values of nitrogen presence or soil nutrient content are relatively equivalent and characterize moderately rich soils. Studies show that biodiversity after the establishment of a tree plantation depends on the land use before its establishment (Bremer & Farley, 2010). The influence of initial ground cover vegetation decreases with increasing tree age. Light-demanding species most often form the ground cover plant composition at the early age of the stand, while as the stand age increases, the number of shade-tolerant plant species increases (Pučka et al., 2016).

Figure 5
The average values of environmental factors

Conclusions

1. The differences between the number of plant species and the average projective cover (%) indicators in *Alnus glutinosa* (L.) Gaertn and *Betula pendula* Roth plots are not statistically significant.
2. Greater plant species diversity was found in *Alnus glutinosa* plots.
3. Ellenberg values in all plots indicate semi-light conditions, moderately moist and acidic soil, and moderately rich in nutrients.
4. In *Alnus glutinosa* and *Betula pendula* stands, no significant effect of a tree species was found on the diversity of ground cover vegetation.

OCCURRENCE PATTERNS OF KEY NON-TIMBER FOREST PRODUCTS: EVIDENCE FROM THE NATIONAL FOREST INVENTORY IN LATVIA

***Agita Treimane[1,2], Jānis Donis[1], Ilze Barone[1], Zane Lībiete[1]**
[1]Latvian State Forest Research Institute 'Silava', Latvia
[2]Latvia University of Life Sciences and Technologies, Latvia

Abstract
Non-timber forest products (NTFPs) are a significant forest ecosystem service, especially with the growing societal importance of forests not only as a timber source but as a multifunctional ecosystem. However, quantitative information on the topic in Latvia is still scarce. Drawing on an extensive National Forest Inventory dataset (4,916 plots), we explored the occurrence, mean cover, and mean height of eight ground vegetation species commonly used as NTFPs and correlated these indices with the forest site characteristics (trophic conditions and soil moisture level) and stand parameters. The most frequently recorded species were *Vaccinium myrtillus, Vaccinium vitis-idaea,* and *Rubus idaeu*s, found in 31.8%, 23.8%, and 19.5% of all plots, respectively. The cover and height of NTFPs were significantly influenced by both site conditions (soil fertility and moisture) and stand structure (age, density, and tree species composition), with strong interdependencies between these factors. The projective cover of most species was significantly influenced by the dominant tree species, stand density, and site trophic level. In contrast, the hydrological factor had a significant effect only on *Vaccinium myrtilus, Fragaria* spp, and lichens. The cover of *Vaccinium vitis-idaea* and *Calluna vulgaris* was statistically significantly negatively affected by stand age and stand density. The cover of *Vaccinium* species, *Fragaria* spp., lichens, and also *Calluna vulgaris* was positively influenced by the dominant tree species *Pinus sylvestris.* Furthermore, data on the overall status of NTFPs in the country provide a foundation for evaluating how different forest management approaches influence the long-term availability and dynamic trends of these resources.
Keywords: ground vegetation, forest berries, stand structure, site conditions.

Introduction

Forests, the most widespread terrestrial ecosystems, offer a wide range of benefits for society. While timber and firewood are most closely associated with the term 'forest resources', non-timber forest products (NTFPs) contribute significantly to people's well-being globally and in the Nordic-Baltic region. FAO defines these products as 'goods of biological origin other than wood derived from forests and other wooded land and trees outside forests' (FAO, 1999), and they include food and food additives, medicinal, cosmetic and decorative resources and fibres. These products are highly important in the European context - at least 100 million Europeans consume various NTFPs, but at least 65 million engage in their collection (Schulp et al., 2014). NTFPs are a crucial part of multi-purpose forestry, even though conflicts with certain forest management approaches exist (Lõhmus & Remm 2017; Kurttila et al., 2018). Foraging for NTFPs often creates a synergy with forest recreation (Kangas & Niemeläinen, 1996; Stryamets et al., 2015; Wiersum, 2017). Moreover, mushroom and berry picking are deeply rooted cultural practices, widely studied in Northern Europe, the Baltics, Central Europe and Western Europe (Pouta et al., 2006; de Aragon et al., 2011; Sisak et al., 2016; Grivins & Tisenkopfs, 2018). In Latvia, NTFPs have high socioeconomic and cultural meaning. According to previously published data from various sources, over 60% of households engage in NTFP gathering (Lovrić et al., 2020; Donis, 2020, 2024). According to Lovrić et al. (2020), *Vaccinium vitis-idaea* and *Vaccinium myrtillus* are the most frequently picked wild berries in Northern Europe. Other species with good potential for picking are *Vaccinium uliginosum* and *Rubus idaeus*. In Latvia, historically important NTFP resources in swampy areas are *Oxycoccus palustris* and *Oxycoccus microcarpus*. While repeated surveys show decreasing NTFPs retail sales (Bārdule et al., 2020), a minor part of the population, especially in the rural areas, still largely rely on the added income provided by the sales of forest berries and mushrooms (Donis, 2024). For the majority of NTFP foragers, however, this activity bears both provisioning and recreational meaning and constitutes a lifestyle aspect rather than a practical necessity (Lībiete, 2023).

While foraging may be a predominantly recreational activity, the availability of the NTFPs is still an essential factor determining the forest visitors' satisfaction with the outdoor experience. The occurrence and abundance of plants, mushrooms, and other organisms depend on the habitat, as well as meteorological conditions. Light availability, site fertility, and soil moisture, as well as management-induced disturbances, are the major factors determining the composition of ground vegetation, including NTFPs (Tonteri et al., 2016, Eldegard et al., 2019; Matisone et al., 2023).

Despite their acknowledged importance, nationwide data on the actual occurrence and cover of NTFPs are scarce. Our study aims to address this knowledge gap by examining the relationships among site conditions, stand structure, and the cover and height of the eight most common NTFPs—*Vaccinium myrtillus, Vaccinium vitis-idaea, Vaccinium uliginosum, Rubus idaeus*, other *Rubus* species*, Fragaria* spp., *Calluna vulgaris*, and lichens.

Materials and Methods

The study is based on data from the NTFP assessment

of the Latvian National Forest Inventory (NFI). The NFI in Latvia is a systematic, nationwide grid-based network of permanent sample plots measured at five-year intervals (circular plots with 500 m² area, 4 plots per tract, tracts are located in 4 × 4 km grid). Within the 500 m² plot, all trees with a diameter at breast height (DBH) ≥ 14.1 cm are measured; within the inner 100 m² circular plot, all trees with DBH ≥ 6.1 cm are measured; within one quarter of the inner plot (25 m²), trees with DBH ≥ 2.1 are measured.

NTFPs have been assessed on NFI plots since 2008. The assessment is conducted in 3 × 3 m rectangular plots located at the center of the 500 m² circular plot. Following species, comprising edible, medicinal, and decorative plants, are recorded*: Vaccinium myrtillus, Vaccinium vitis-idaea, Vaccinium uliginosum, Rubus idaeus, Rubus caesius, Rubus nessensis, Rubus plicatus, Rubus odoratus, Fragaria vesca, Fragaria viridis, Calluna vulgaris* and lichens (*Cladonia sp., Cetraria islandica*). Although *Fragaria vesca* is the most likely species in forest habitats, the NFI field assessments identify these species only at the genus level. Within each subplot, species-level projective cover (%) is recorded, along with modal height (in 0.05 m classes) and, during the reproductive season, the presence of flowers or fruits (berries).

This study used data from one complete NFI cycle (2019–2023), comprising 4916 plots located in forest land and clear-felling areas (forest land categories 10 and 14). The sample covered a wide range of site conditions, including gradients of soil fertility (from oligotrophic to eutrophic) and soil moisture (dry, mesic, and wet), as well as variation in stand age and stand density. Species' projective cover and height were analysed using generalized linear mixed models (*GLMMs)* fitted in R (version 4.2.2) with the *glmm*TMB package. Because the cover data were strictly positive and right-skewed, a *Tweedie* distribution with a log link function was applied, which is suitable for continuous, positive ecological data with heterogeneous variance.

For cover-intensity analyses, only positive observations (cover > 0) were included, thereby modelling cover magnitude conditional on species presence. Fixed effects comprised site characteristics—soil fertility (from oligotrophic to eutrophic) and soil moisture (dry, mesic, and wet)—as well as stand structural variables: relative density of the first and second canopy layers, stand age, and dominant tree species group. Tract identity was included as a random intercept to account for repeated measurements and potential non-independence of observations within plots.

Inference was based primarily on effect size estimates and their 95% confidence intervals. Where multiple comparisons were performed, p-values were adjusted using the false discovery rate (FDR) approach.

All data processing and visualization were done in RStudio, version 4.2.2.

Results and Discussion

At least one of all studied NTFPs was found on 2978 plots (60.6% of all plots). The most frequently recorded species were *Vaccinium myrtillus*, *Vaccinium vitis-idaea* and *Rubus idaeus*, found on 1,609, 1,173, and 931 plots (31.8%, 23.8%, and 19.5%, respectively). Other species were recorded on less than 10 percent (from 7.6% to 0.8%) of the plots (Table 1). The highest mean cover was recorded for *Rubus* spp. *Vaccinium myrtillus*, *Vaccinium uliginosum*, and *Rubus idaeu*s. The mean height varied most for *Rubus idaeu*s (from 0.05 m to 2.2 m), indicating that these species might rely the most on varying site conditions and stand parameters.

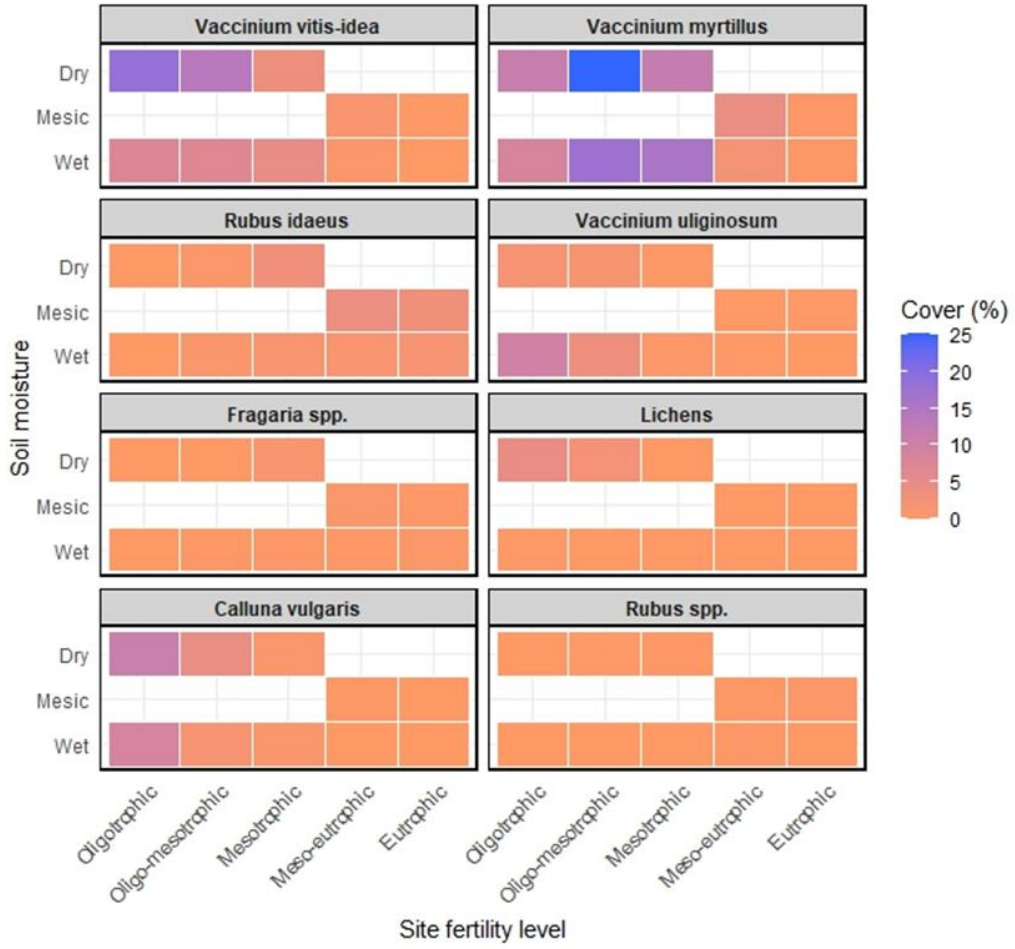

Table 1

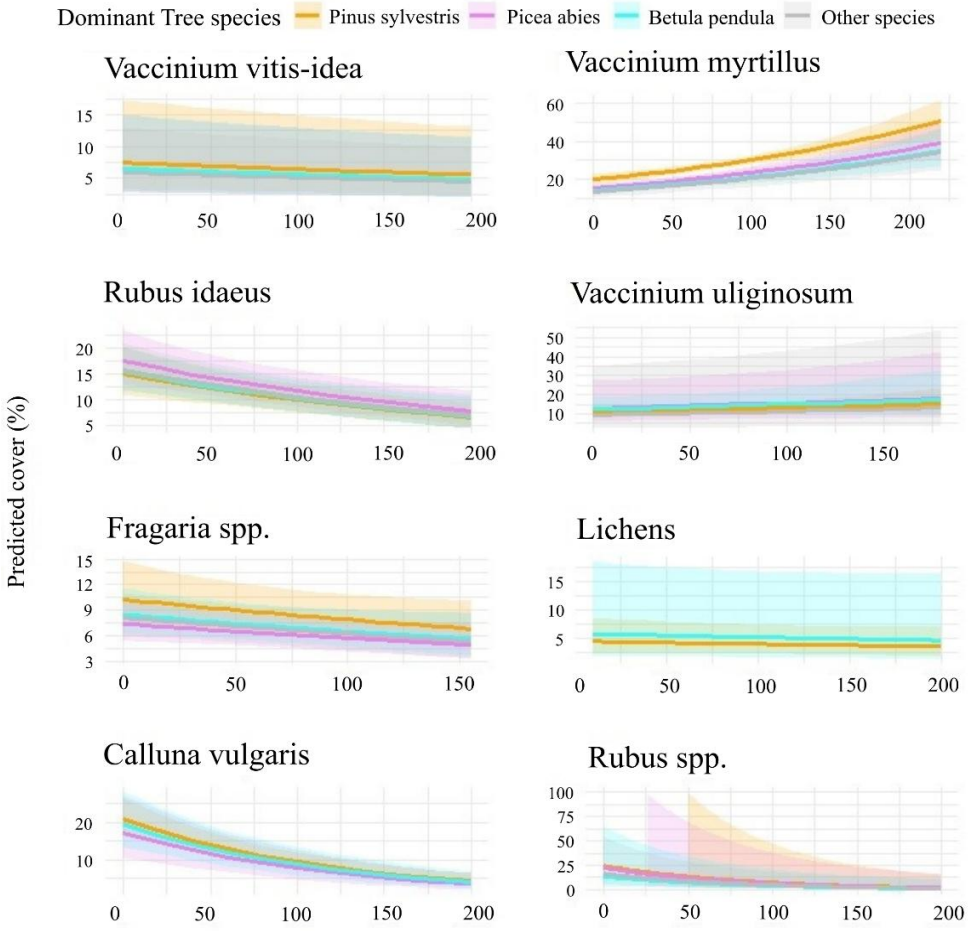
Occurrence, mean cover, mean height, and predominant site conditions characterizing the studied NTFPs

NTFP	Occurrence, % (number of plots)	Mean cover, %, where species was present	Mean height, cm	Predominant site conditions (fertility level/moisture)
Vaccinium myrtillus	31.81/1609	25.22±0.44	20.55±0.17	Mesotrophic/Dry
Vaccinium vitis-idaea	23.82/1173	14.72±0.27	12.63±0.14	Oligo-mesotrophic/Dry
Vaccinium uliginosum	4.39/216	18.93±0.35	40.31±0.79	Oligo-mesotrophic/Wet
Rubus idaeus	19.47/931	16.31±0.33	64.5±1.15	Meso-eutrophic/Mesic
Rubus spp.	0.85/43	38.7±2.19	46.78±0.4	Meso-eutrophic/Wet
Fragaria spp.	7.57/369	9.62±0.18	12.56±0.02	Meso-eutrophic/Mesic
Calluna vulgaris	6.98/337	18.25±0.38	25.14±0.1	Oligo-mesotrophic/Dry
Lichens	1.52/73	17.46±0.38	-	Oligo-mesotrophic/Dry

The highest occurrence and cover were determined by each species' ecological requirements and adaptive capacity. *Vaccinium vitis-idaea* was one of the most frequently observed (and with the highest cover) in dry oligotrophic forest stands. In contrast, *Vaccinium myrtillus* was characteristic of slightly more fertile sites and occurred in both dry and wet conditions (Figure 1).

Figure 1
Predicted cover (%) of the studied NWFPs, by soil moisture and site fertility level, %

The model results indicated that the significant factors affecting projected cover differed across the analysed species. For example, for *Vaccinium myrtillus*, in contrast with the other species, the factor that positively influenced cover was the dominance of *Pinus sylvestris* in the main stand compared to spruce (β= -0.385, $p < 0.001$), birch (β=-0.950, $p < 0.001$), and other species (β=, -1.887, $p < 0.001$) (Figure 2). This is consistent with the results from Northern European studies where higher *Vaccinium myrtillus* cover was found in *Pinus*-dominated forests compared to *Picea*-dominated ones (Eldegard et al., 2019; Miina et al., 2009), while deciduous trees decreased *Vaccinium myrtillus* cover, especially on the most fertile mineral soil sites. (Turtiainen et al., 2016). In our study, stand age showed a weak but significant positive effect on *Vaccinium myrtillus* cover ($\beta = 0.012$, $p < 0.001$), whereas, compared to the reference trophic group (eutrophic forest soils), the cover of *Vaccinium myrtillus* was significantly higher in the mesotrophic group ($\beta = 3.305$, $p < 0.001$), the mesoeutrophic group ($\beta = 2.318$, $p < 0.001$), the oligomesotrophic group ($\beta = 3.539$, $p < 0.001$), and the oligotrophic group ($\beta = 2.334$, $p < 0.001$).



The predicted increase was gradual, indicating that older forests provided more favourable conditions for *Vaccinium myrtillus*. Similar results have been reported by Eldegard et al. (2019) in a Norwegian study, where an increase in *Vaccinium myrtillus* cover was observed in older stands. For *Rubus idaeus*, however, the negatively influencing factor was stand age (β = -0,173, $p < 0.001$) – its cover declined as stand age increased, and the trend was similar in oligotrophic and oligo-mesotrophic conditions. This confirms that this species is characteristic for early successional stages of the forest. *Rubus idaeus* often becomes dominant within 2–3 years after major over-story disturbances (e.g., clear-cutting) in mesic temperate forests (Donoso & Nyland, 2006). The abundance of shrubs decreases rapidly as the stand canopy closes at 30 years of age (Kardell, 1979). However, our results indicate a more gradual and consistent decline rather

than an abrupt reduction.

Calluna vulgaris is commonly found in dry pine forests, clear-cuts, bogs, and acidic, nutrient-poor soils. In our study, it was positively associated with *Pinus sylvestris* stands, compared to *Picea abies* ($\beta = -1.995$, $p < 0.001$) or *Betula* spp. ($\beta = -1.736$, $p < 0.001$), but negatively associated with stand density and stand age ($\beta = -0.016$, $p < 0.001$).

Figure 2

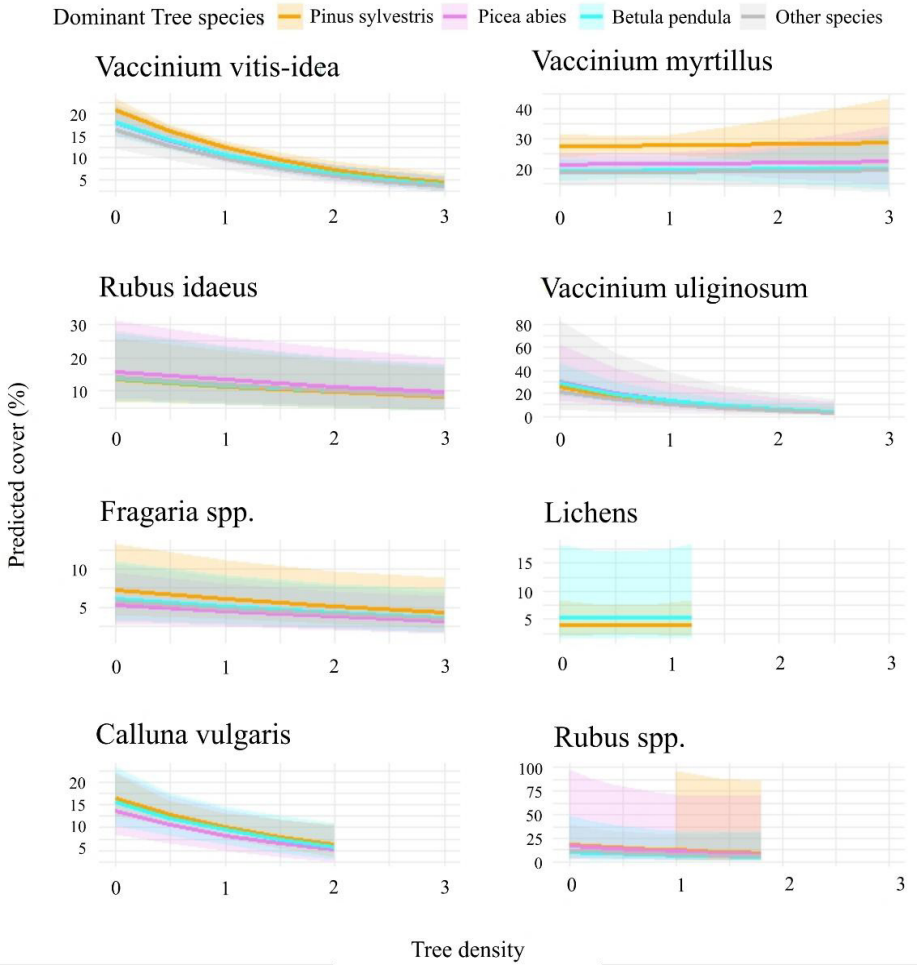
Predicted cover (%) of the studied NTFPs depending on the age of the dominant stand tree species. Graphs show the results of the glmmTMB models

Note: the scales for predicted cover (%) and stand age (years) differ among species.

Comparing changes in projective cover in relation to stand age and stand density, it was evident that stand density did not significantly affect ($\beta = 0.161$, $p < 0.001$) the *Vaccinium myrtillus* cover.

A study conducted in Lithuania on the vegetation succession in pine stands concluded that the highest cover of *Calluna vulgaris* occurred in the early stages of stand development, when stand density was relatively low (Gustienė et al., 2022). It has been found that the optimal stand relative density for *Vaccinium vitis-idaea* ranges from 0.1 to 0.3, at which the species attains its highest projective cover (Timoshok, 2000).

The model results indicated that the factors significantly affecting the projected height differed among the analyzed species and the dominant tree species. For *Vaccinium myrtillus*, a gradual increase in predicted height was observed with increasing stand age ($\beta = 0.161$, $p < 0.001$). Statistically significant differences between stand age and height were observed for *Vaccinium myrtillus* ($\beta = 0.001$, $p < 0.001$), *Rubus idaeus* ($\beta = 0.001$, $p < 0.001$), other *Rubus* spp. ($\beta = 0.001$, $p < 0.001$), and *Calluna vulgaris* ($\beta = -0.001$, $p < 0.001$) (Figure 4).



Predicting optimal forest characteristics for NTFPs is of general ecological interest and importance for sustainable and well-balanced forest management. Based on a nationwide dataset of sample plots across different forest type groups, we demonstrate that the effects of stand age and stand density on species cover and height are also influenced by tree species composition, hydrological conditions, and trophic groups.

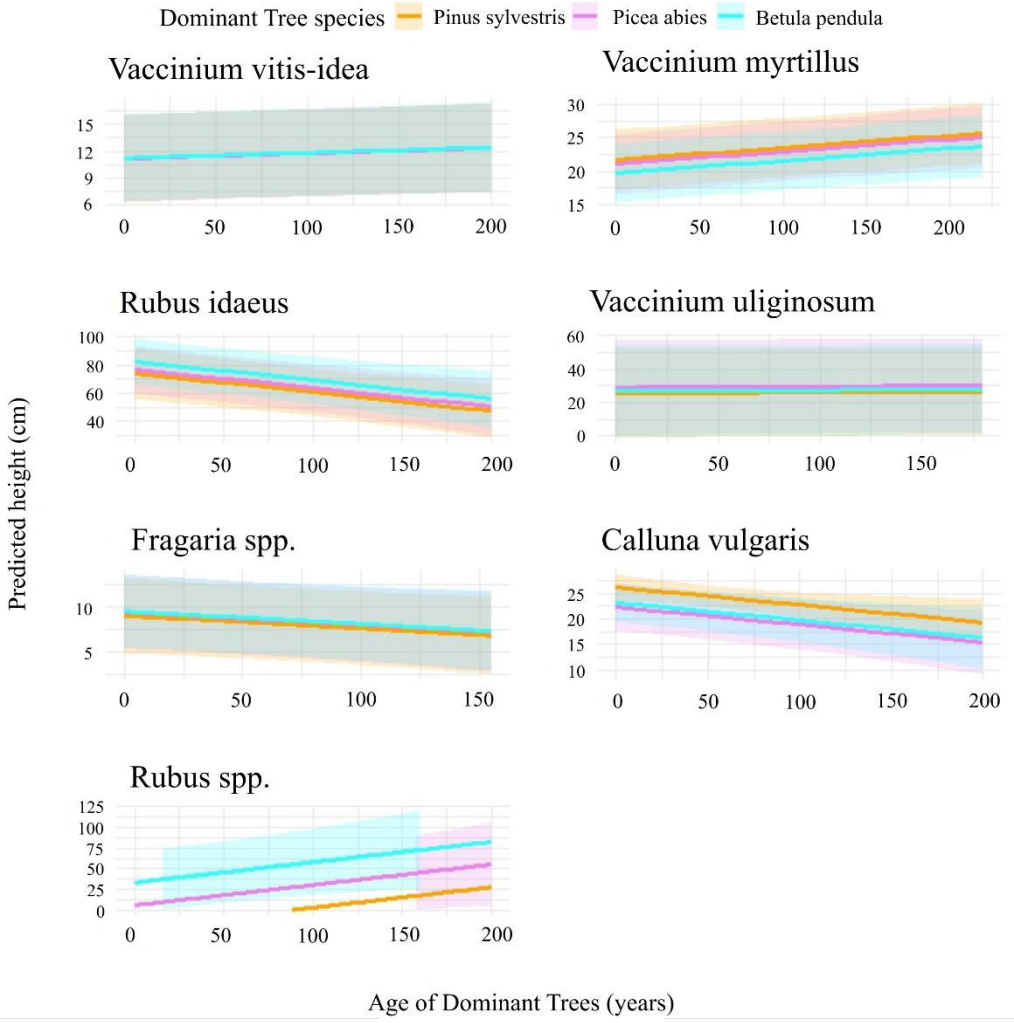
Due to data availability and time constraints, this

study primarily focused on forest berries and did not include other important non-wood forest products, such as mushrooms, which require significantly longer time series due to high yield variation resulting from a complex interaction of meteorological factors (Dahl et al., 2008, Olah et al., 2020). Nevertheless, the results indicate the presence of non-wood forest products in Latvian forest stands, including those where clear-cut regeneration has been applied.

Figure 3

Predicted cover (%) of the studied NTFPs depending on the tree density (relative tree density according to local legislation) of the dominant stand tree species. Graphs show the results of the glmmTMB models

Note: the predicted cover (%) scale differs among species.



The findings of this study represent the overall condition of NTFPs in the country. These data can serve as a baseline, complemented by berry yield data and factors driving annual variation, for further analysis and assessment. Furthermore, the data on the overall status of NTFPs in the country provide a foundation for evaluating how different forest management approaches influence the long-term availability and dynamic trends of NTFPs.

Conclusions

1. Most frequently recorded forest berry species in Latvia are *Vaccinium myrtillus*, *Vaccinium vitis-idaea*, and *Rubus idaeus,* while the remaining species are recorded much less frequently, reflecting their narrower ecological niches.
2. The highest average projected cover of *Vaccinium myrtillus* and *Vaccinium vitis-idaea* is observed in the dry forest group, from oligotrophic to mesotrophic forests.
3. Both tested variables (projective cover and height) of the studied NTFPs vary significantly among the tested sites. The cover of NTFPs is explained by a broader range of factors than height, suggesting that cover is a more sensitive indicator of changes in environmental conditions and stand structure
4. Strong relationships exist between site conditions and stand structure: specific site conditions determine the formation of characteristic stand types (e.g., the dominance of pine on nutrient-poor soils), which, in turn, affect the cover and height of NTFP species. The cover and height of NTFPs are significantly influenced by both site conditions and stand structure, which are closely interrelated and collectively influence NTFP occurrence and characteristics.

SNOW, WATER, AND TERRAIN AS DRIVERS OF FOREST SCENIC BEAUTY

***Zane Lībiete, Edgars Jūrmalis**

Abstract
Understanding outdoor visitors' preferences can support spatial planning and management of nature areas. Prior research suggests that distinct environmental features—such as snow cover, topographic variation, and nearby water—can increase visual appeal by adding contrast, depth, and recognizable focal points. To assess the effects of these three elements on the aesthetic evaluation of five forest landscape types among the Latvian population, we conducted a nationwide representative online survey (CAWI; n = 1001). Respondents rated photographs on a 7-point Likert scale using paired comparisons across five forest setting types: pine stand, spruce stand, broadleaved stand, clear-cut area, and forest road. For each setting type, participants evaluated matched photo pairs where one image included a target element (snow, water, or terrain variation) and the other did not. Internal consistency of ratings was examined using reliability analysis, and paired differences between image versions were tested with the Wilcoxon signed-rank test. All analyses were performed in IBM SPSS Statistics v26. Across all conditions, pine stands received the highest ratings, while clear-cut areas were rated lowest. The presence of the tested elements generally increased ratings across setting types, but effects varied in magnitude. Differences were most pronounced for spruce and broadleaved stands, where images featuring snow, terrain variation, or water were rated notably higher than their matched counterparts without these elements. Overall, the findings underline the role of salient visual features as cues that can measurably enhance perceived attractiveness, offering practical entry points for improving perceived amenity through planning and design.
Keywords: landscape amenity, visual preference, forest setting, paired comparisons, societal survey.

Introduction

Understanding preferences for different outdoor settings is essential for managing visitor flows in nature areas, particularly when the goal is to protect sensitive sites or plan management interventions in time and space. Previous research indicates that landscape elements (e.g., terrain, presence of waterbodies), seasonality (including phenological changes, notably autumn and winter), and meteorological conditions (such as snow cover or extreme temperatures) can significantly influence visitors' perceptions of natural environments (Pálsdóttir, 2009; Korpela et al., 2010; Jaal et al., 2013; Tyrväinen et al., 2017; Ebenberger & Arnberger, 2019; Wang et al., 2020).

Snow cover enhances the visual attractiveness of forested areas by creating a picturesque, peaceful environment often associated with harmony and beauty. Studies suggest that viewing snow-covered landscapes may also improve mood (Bielinis et al., 2021). In forest settings, the bright white snow contrasts with darker tree tones, increasing visual appeal. This transformation may attract more visitors during winter, as people seek scenic views, photography opportunities, and winter recreation (Xiao et al., 2015; Bausch & Unseld, 2017).

The presence of waterbodies in forests increases scenic beauty and provides opportunities for activities such as fishing, boating, and swimming. Water can enhance outdoor experiences by evoking peace and relaxation or by offering possibilities for active recreation. People are naturally drawn to water, and its presence can elevate the overall scenic quality of a landscape while supporting diverse habitats that attract wildlife enthusiasts and photographers (Kakoyannis, 2002; Mundher et al., 2022).

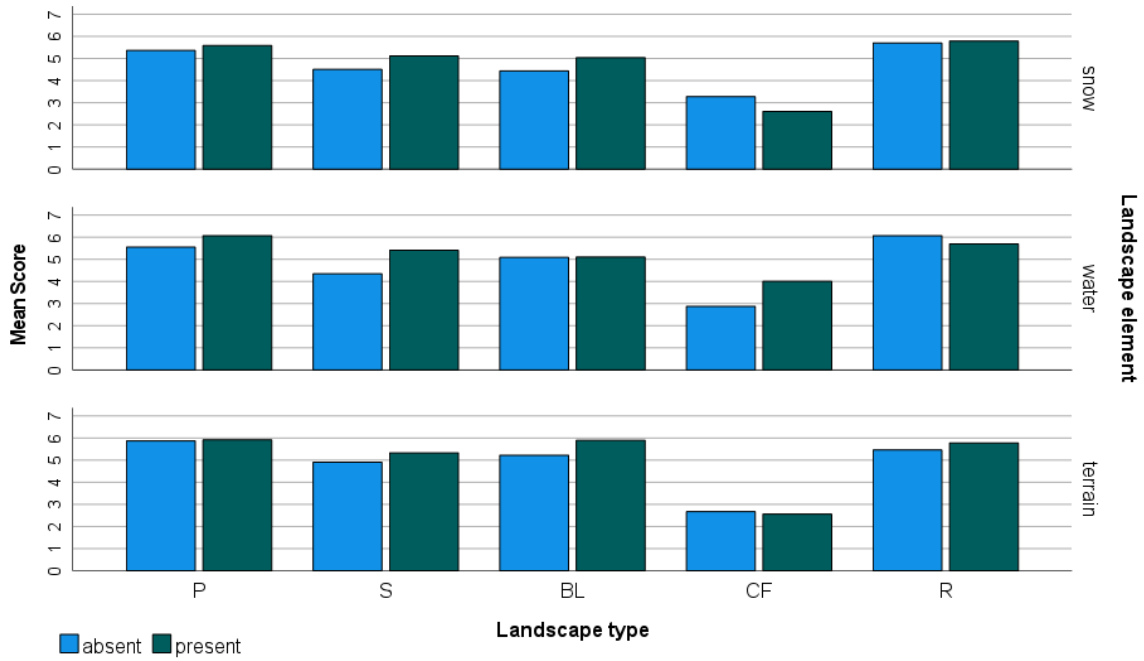
Terrain variability - hills, valleys, and other topographic features - also contributes to the aesthetic and recreational value of forested areas. Pronounced and diverse terrain creates a more dynamic and engaging landscape compared to flat, uniform sites. Such diversity supports activities like hiking, mountain biking, and climbing, while also increasing the variety of viewpoints and, consequently, the scenic quality of the forest (Golovets, 2011).

Although the importance of landscape elements in shaping visitors' perceptions is widely acknowledged, detailed empirical studies remain comparatively scarce. The objective of this study was to assess the effects of snow cover, waterbody presence, and terrain variability on the aesthetic evaluation of five forest landscape types among the Latvian population.

Materials and Methods

Data were collected in autumn 2024 through an online survey (CAWI; n = 1001) administered by a professional survey company to a nationally representative sample of respondents (balanced by gender, age, and place of residence). Participants evaluated photographs of forest landscapes using a 7-point Likert scale (1 – dislike a lot … 7 – like a lot). The photo set included five forest landscape types: pine forest, spruce forest, broadleaved forest, clearfelling area, and forest road. Each landscape type contained three pairs of photographs showing the presence or absence of a specific landscape element (snow, terrain variability, waterbody). All other attributes within each pair - such as forest type, stand age, stand density, and lighting - were kept as similar as possible. We selected forest types typical of Latvia (medium fertility and soil moisture) with normal stand density (7–8) and medium-aged to mature stands. To avoid copyright issues, all photographs were taken by the authors. An example photo pair is shown in Figure 1. Photographs were presented in random order, and all respondents rated all pairs.

Figure 1
Example of photos used for the evaluation in category 'Forest road' (left – with snow, right – without snow)



To assess the internal consistency of the evaluation items, we conducted a reliability analysis using Cronbach's alpha, which confirmed that the photo-based Likert-scale ratings were sufficiently reliable for subsequent statistical testing. Differences in perceived landscape value between photos with and without each environmental element were analysed using the Wilcoxon signed-rank test, an appropriate non-parametric method for paired ordinal data. All data processing and statistical analyses were performed in IBM SPSS Statistics v27.

Results and Discussion

Cronbach's alpha was 0.926, indicating very high internal consistency of the evaluation scores.

Across all forest landscape photographs, pine stands and forest roads received the highest ratings, while clearfelling areas were evaluated the lowest. These results align with previous findings from the Nordic–Baltic region (e.g., Silvennoinen et al., 2010; Tyrväinen et al., 2017). In most cases, the presence of a landscape element increased the assigned score. The largest difference in mean scores (1.1 points) was observed when comparing spruce forests and clearfelling areas with and without a waterbody. The smallest differences were found for forest roads with or without snow, broadleaved forests with or without a waterbody, and pine forests with or without terrain (Figure 2).

Figure 2
Mean evaluation scores with the tested landscape element absent and present across the assessed forest landscapes

Median values indicated generally positive attitudes toward all forest landscape types. For pine forests, broadleaved forests, and forest roads, the dominant rating was 'like', regardless of the landscape element. Attitudes toward spruce forests were less positive, with more frequent 'neutral' or 'rather dislike' responses. Clearfelling areas were evaluated most negatively, with dominant ratings of 'dislike' and 'rather dislike' (Table 1).

Figure 3
Distribution of the evaluation scores across forest landscape types and landscape elements

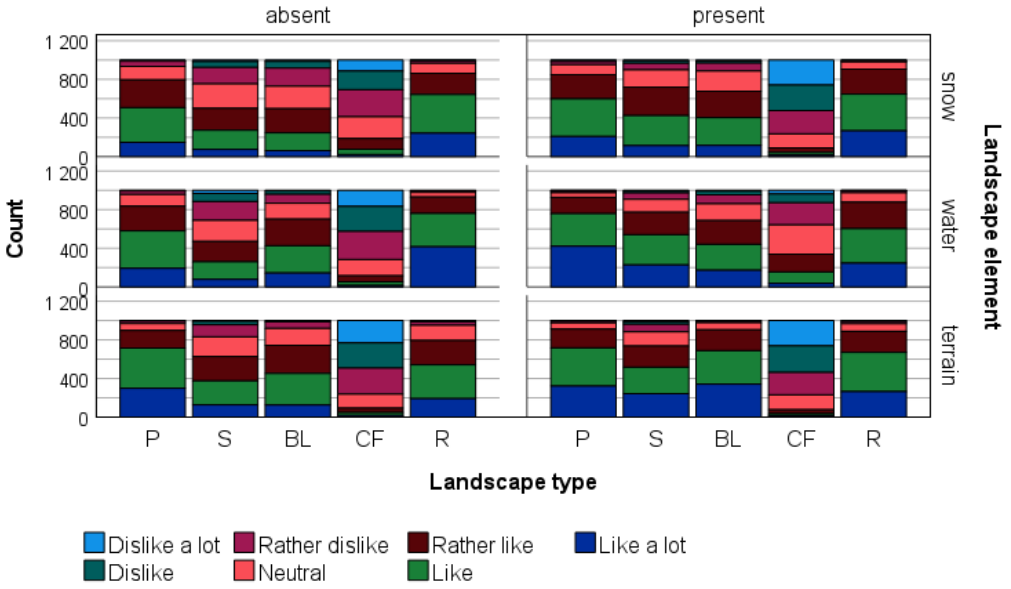


Table 1
Descriptive statistics of scores assigned to photos with or without the tested elements across landscape types

Landscape type	Element (S – snow, W – water, T – terrain)	Descriptive statistics of the scores (element present/element absent)				
		Mean	St. error of mean	Median	Mode	St. dev.
Pine forest	S	5.58/5.37	0.036/0.036	6.00/6.00	6/6	1.140/1.150
	W	6.07/5.55	0.033/0.035	6.00/6.00	7/6	1.041/1.095
	T	5.92/5.87	0.032/0.033	6.00/6.00	6/6	1.023/1.050
Spruce forest	S	5.12/4.51	0.039/0.045	5.00/4.00	6/4	1.249/1.409
	W	5.42/4.36	0.042/0.048	6.00/4.00	6/4	1.326/1.533
	T	5.34/4.92	0.045/0.043	6.00/5.00	6/5	1.422/1.375
Broadleaved forest	S	5.04/4.43	0.041/0.044	5.00/4.00	6/5	1.284/1.398
	W	5.11/5.08	0.044/0.042	5.00/5.00	6/6	1.404/1.343
	T	5.91/5.22	0.033/0.037	6.00/5.00	7/6	1.049/1.166
Clearfelling area	S	2.61/3.28	0.045/0.046	2.00/3.00	2/3	1.415/1.450
	W	4.01/2.87	0.044/0.044	4.00/3.00	4/3	1.391/1.387
	T	2.57/2.67	0.044/0.045	2.00/3.00	2/3	1.382/1.412
Forest road	S	5.79/5.70	0.032/0.034	6.00/6.00	6/6	1.026/1.087
	W	5.70/6.08	0.033/0.033	6.00/6.00	6/7	1.042/1.030
	T	5.78/5.45	0.034/0.037	6.00/6.00	6/6	1.063/1.160

Within each landscape type, pine forests showed the most consistent evaluations, with minimal differences between photos with and without snow, terrain, or water. The opposite pattern emerged for spruce forests: settings without landscape elements were often rated neutral or negative, while the presence of snow, terrain, or water substantially increased positive evaluations. A similar trend was observed for broadleaved forests. In clearfelling areas, snow cover slightly reduced ratings, whereas waterbody presence increased the proportion of neutral responses and reduced negative ones. This 'inverted' effect of snow may be explained by the thin snow cover and visible logging residues in the photographs. For forest roads, terrain had the strongest positive effect, increasing the share of moderately to highly positive ratings (Figure 3). Overall, these results suggest that landscape elements matter, but their influence is not uniform: when the 'base setting' is already well-liked, additional elements have a smaller effect than in less preferred settings such as spruce forests.

In nearly all landscape types, photos with the tested landscape element received higher ratings. In all cases except pine forests with or without terrain and

broadleaved forests with or without a waterbody, the differences were statistically significant ($p < 0.05$; Table 2). Forest roads showed the smallest influence of landscape elements: in all three photo pairs, more than 40% of respondents assigned identical scores. In contrast, for spruce forests, more than 40% of respondents rated the element-present photos higher across all three elements (snow, terrain, water).

When examining the landscape elements separately, waterbody presence emerged as the strongest driver of increased aesthetic value, raising scores by +1.14 points for clearfelling areas. Snow produced small to moderate increases in pine, spruce, and broadleaved forests and forest roads, but decreased ratings for clearfelling areas (-0.67). Terrain had the strongest positive effect in broadleaved forests (+0.69) and forest roads (+0.33), with minimal impact in pine forests and a slight negative effect in clearfelling areas. Overall, aesthetic evaluations were similar across socio-demographic groups, with some exceptions. Respondents from the capital city Riga and the surrounding Pieriga region showed larger score differences between photos with and without landscape elements, with statistically significant differences in all cases except forest roads with or without snow.

Table 2

Score differences of the photo pairs (element present vs. element absent), Wilcoxon signed-rank test results

Landscape type	Element (S – snow, W – water, T – terrain)	Z-value	p-value
Pine forest	S	-6.734	<0.001
	W	-12.556	<0.001
	T	-1.927	0.054
Spruce forest	S	-13.079	<0.001
	W	-18.479	<0.001
	T	-8.995	<0.001
Broadleaved forest	S	-13.608	<0.001
	W	-0.9	0.368
	T	-15.129	<0.001
Clearfelling area	S	-16.426	<0.001
	W	-18.359	<0.001
	T	-3.621	<0.001
Forest road	S	-2.464	0.014
	W	-10.571	<0.001
	T	-9.351	<0.001

The consistent positive effects of snow, terrain, and waterbody presence on perceived aesthetic value suggest several practical implications for forest management. Pine forests are generally well-liked (as also shown by Silvennoinen et al., 2001), but in spruce-dominated areas with monotonous views, designing for visible waterbodies or highlighting terrain features may enhance perceived attractiveness. Waterbodies may also soften negative perceptions of clearfelling areas, whereas snow does not necessarily improve their appearance - suggesting that winter recreation routes near recent clearcuts may reduce visitor satisfaction. It should be noted that the example used in this study depicted a thin snow cover, which is increasingly common under current climatic conditions; thicker snow may have a more positive effect (Tyrväinen et al., 2017). Waterbodies are widely associated with positive affect and restorative qualities in both natural and built environments (White et al., 2010). However, their aesthetic contribution depends on their recognizability as natural blue spaces; artificial ditches or straightened channels may not enhance visitor experience (Grace et al., 2023).

This study has several limitations. Although the photographs represented typical Latvian forest settings and were matched as closely as possible within each pair, it is still possible that factors other than the tested landscape element influenced the ratings. Visual materials inherently introduce additional evaluative cues such as viewing angle, composition, rhythm, colour tones, and lighting (Sevenant & Antrop, 2011). Even carefully matched photo pairs may differ subtly in attributes such as path curvature, sky visibility, or understorey structure, which can affect evaluations (Palmer & Hoffman 2001). Moreover, personal associations, memories, and value systems may shape individual responses, with some studies identifying visitor characteristics as key determinants of perceived visual attractiveness (e.g., Kearney & Bradley, 2010; Hegetschweiler et al., 2022). Homogeneity of landscape has been perceived negatively in some cases; thus, a broader, holistic study at the landscape level would be prudent in determining preferences (Schirpke et al., 2013). Photo-based surveys capture only visual information, whereas on-site experiences include sound, smell, temperature, wind, movement,

and perceived safety, all of which may influence landscape perception (Hull & Stewart, 1992). Future research on forest amenity values could therefore benefit from more immersive technologies such as 360° imagery, video, or virtual reality, which have shown promise in landscape assessment (Shi et al., 2020).

Conclusions

1. Pine forests received the highest aesthetic ratings but clearfelling areas the lowest, regardless of the presence of landscape elements.
2. Snow cover, waterbody presence, and terrain variability generally increased the stated aesthetic quality of forest landscapes, with waterbody presence showing the strongest positive effect and only a few exceptions across landscape types.
3. Among the three tested elements, waterbody presence had the strongest positive effect on aesthetic ratings; snow cover produced small to moderate increases in most forest types but reduced ratings for clearfelling areas; terrain variability had the strongest positive effect in broadleaved forests and forest roads.
4. Residents of the capital city and its surrounding region rated element-present images considerably higher than residents of other areas.
5. The aesthetic effects of snow cover, waterbody presence, and terrain variability differed across forest landscape types, with the most pronounced responses observed for spruce and broadleaved forests.

Abstract
Far-red light has emerged as an important spectral component in plant tissue culture, affecting morphogenesis and physiological development. Supplementation with far-red light lowers the red:far-red (R:Fr) ratio perceived by plantlets, promoting stem elongation, internode extension, apical dominance and leaf expansion traits often desirable during the shoot multiplication and elongation phases. However, the excessive reduction of R:Fr can induce etiolation, reduced chlorophyll accumulation, and weakened structural tissues. In this study, the performance of *in vitro* cultures of three silver birch clones under LED illumination with R:Fr ratio of ~1.0 was tested. Cultivation in such conditions seemed to partially trigger the expression of shade-avoidance like traits, while maintaining the robustness and photosynthetic capacity of plantlets. More resources were allocated to main shoot growth, while lateral shoot development was inhibited, and propagation rates remained the same. At the same time, relative chlorophyll content (SPAD) was slightly lower, yet photosynthesis worked more efficiently as indicated by higher PI_{ABS}. Quantum yield efficiency (Fv/Fm) for plantlets cultivated under low R:Fr was slightly higher, yet remained above the optimum threshold (0.8) for both treatment and control. These findings demonstrate that far-red light supplementation can be used to manipulate the architecture and physiological performance of *B. pendula in vitro*, promoting elongation and potentially improving transplant-ready morphology, while maintaining efficient photochemical activity and robustness of plantlets.
Keywords: Silver birch, phytochrome signalling, micropropagation, LED, shade-avoidance.

Introduction

Light quality is a critical environmental signal regulating plant growth and development. In natural ecosystems, solar radiation is selectively filtered by vegetation: chlorophyll strongly absorbs red and blue wavelengths, while far-red (Fr) radiation (700–750 nm) is transmitted and reflected (Ballaré et al., 1990). As a result, the red:far-red (R:Fr) ratio declines beneath plant canopies and within dense stands. Plants have evolved to interpret this spectral shift as an indicator of neighbouring vegetation and impending competition for light. A reduced R:Fr ratio, therefore, functions as an ecological signal that enables plants to adjust their growth strategy to optimise light capture and survival (Tan et al., 2022).

Perception of R:Fr changes is mediated by the phytochromes, which exist in two conformations: the red-absorbing Pr and the biologically active Fr-absorbing Pfr (Tan et al., 2022). The relative proportion of these forms reflects the spectral composition of the environment and regulates downstream signalling networks, including hormonal pathways involving auxins, gibberellins, and brassinosteroids (Demotes-Mainard et al., 2016; Wang et al., 2022). Under the reduced R:Fr conditions, phytochrome signalling promotes a suite of morphological and physiological responses commonly associated with shade environments. These include stem and internode elongation, enhanced apical dominance, reduced lateral branching, and altered leaf orientation or expansion (Ballaré et al., 1990; Casal, 2012; Franklin, 2008; Tan et al., 2022). Physiologically, reduced chlorophyll content and shifts in biomass allocation may occur, accompanied by modifications to photosynthetic function (Demotes-Mainard et al., 2016; Evans & Poorter, 2001). However, the magnitude and nature of these responses depend on species, genotype, light intensity, and exposure duration (Demotes-Mainard et al., 2016). Excessive Fr enrichment can induce etiolation, characterised by fragile tissues, diminished structural integrity, and reduced acclimatisation potential (Ballaré & Pierik, 2017).

Light spectrum manipulation is an effective tool for regulating plant architecture in controlled environments (Muleo et al., 2025). In micropropagation, overly compact shoots hinder handling and acclimatisation, while moderate elongation improves transplant readiness and efficiency. The key challenge is to promote elongation without inducing etiolation or reducing physiological performance. Far-red supplementation offers a targeted approach by stimulating axial growth while maintaining structural integrity and photochemical function (Franklin, 2008; Smith, 2000).

Despite increasing interest in spectral optimisation for controlled cultivation, most studies of Fr responses have focused on herbaceous crops and model species (Casal, 2012), while woody plants remain comparatively underexplored. Silver birch (*Betula pendula* Roth.) is an ecologically and economically important forest species in northern Europe, and efficient micropropagation protocols are essential for clonal propagation and breeding programs (Ryynänen L. & Ryynänen M., 1986). However, the effects of reduced R:Fr ratios on shoot architecture and physiological performance in birch microshoot cultures are insufficiently characterised, particularly with respect to maintaining structural integrity and photosynthetic efficiency.

The present study evaluates the effects of reduced R:Fr ratio (~1.0), on the morphology and physiological

performance of *in vitro* cultures of three silver birch clones. Specifically, we examined shoot morphology, chlorophyll status, and photochemical efficiency to determine whether the reduced R:Fr ratio can promote elongation and transplant-ready morphology without inducing etiolation or impairing photosynthetic function.

Materials and Methods

In this study, we used established *in vitro* cultures of three locally bred silver birch clones 54-461, 54-89 and 55-880 from *in vitro* clone archive of Latvian State Forest Research Institute 'Silava' Laboratory of Plant Physiology. Prior to the experiment, the cultures were routinely cultivated in 100 mL glass jars covered with transparent, gas-permeable plastic lids, containing ~20 mL of Woody Plant Medium (WPM) (Lloyd & McCown, 1980) supplemented with 0.1 mg L^{-1} BAP, sucrose 20 g L^{-1} and solidified with 6 g L^{-1} plant agar (SigmaAldrich, USA). Medium pH was adjusted to 5.8 prior to autoclaving (121 °C at 200 kPa for 20 min). Subcultures were carried out by dissecting fully regenerated plantlets into 1.5 cm long explants, either from shoot apex or shoot segments containing at least two leaves. Transplanted explants were then cultivated for six weeks on a vertical shelf system under full-spectrum (control) LED luminaires (Table 1) with total photosynthetic photon flux density (PPFD) 30±2 µmol m^{-2} s^{-1} and a 16/8h (day/night) photoperiod. The temperature in the growth chamber was maintained at 25 °C and relative air humidity at 30-40%.

Table 1

Photosynthetic photon flux density (µmol m^{-2} s^{-1}) distribution over spectral regions for luminaires used in this study and the relevant light ratios analysed

Spectral regions and relevant spectral ratios	Reduced R:Fr	Control
blue (B) (400-500 nm)	3.3	5.4
green (G) (500-570 nm)	2.6	3.9
yellow + orange (570-625 nm)	2.2	3.4
red (R) (625-700 nm)	10.8	16.8
far-red (Fr) (700-750 nm)	11.1	0.5
Total PPFD in PAR region (400-750 nm)	30	30
R:B	3.3	3.1
R:Fr	1.0	31.1
B:G	1.3	1.4

To test the effect of reduced R:Fr ratio, plantlets were cultivated under full-spectrum LED luminaires supplemented with Fr LEDs emitting light at a peak wavelength of 730 nm. The amount of Fr light was adjusted so that R:Fr reduced to ~1.0, while other significant light ratios (R:B, B:G) and total PPFD were maintained the same as for the control group (Table 1). As control, plantlets under spectral composition used for routine propagation purposes were cultivated. Spectral composition and PPFD were measured using an AvaSpec ULS2048 spectrometer (Avantes, The Netherlands). All other growth conditions were maintained the same as mentioned before.

After cultivation for 6 weeks, morphological characteristics of the plantlets – main shoot traits (length, number of internodes and average internode length), lateral shoot traits (number and length of shoots) and rooting rate of plantlets were evaluated. Using measurements of morphological traits, we calculated: 1) Multiplication index, derived by dividing total shoot length by the mean explant length (1.5 cm); 2) Lateral branching, defined as the percentage of plantlets that developed lateral shoots and 3) Axis Proportion Index (API), calculated by dividing the main shoot length by the total shoot length. The API describes biomass allocation to lateral or main axis, where a value less than 0.5 indicates longer lateral shoots and a value greater than 0.5 indicates a longer main shoot.

Physiological traits were assessed in the same plants alongside morphological measurements. Relative chlorophyll content (SPAD) was measured as an indicator of photosynthetic capacity using Minolta SPAD-502 (Konica Minolta, Japan). Mean value of 5 measurements was taken from the largest of newly formed leaves for each plant, representing relative chlorophyll content for the whole plant. Chlorophyll a fluorescence was determined using HandyPea portable fluorometer (Hansatech Instruments Ltd., UK) and used to assess the photosynthetic efficiency of plants. The same leaf as for SPAD was used for fluorescence measurements, representing the whole plant. Detached leaves were first dark-acclimated for 15 min, then exposed to short and saturated (1500 µmol m^{-2} s^{-1}) pulse of red light and the reemitted light was measured. Raw data were processed with PEA PLUS v.1.13 (Hansatech Instruments Ltd., UK) and exported as data points. For further analysis, we used fluorescence parameters Fv/Fm (as sensitive indicator of stress) and performance index PI_{ABS} (as a proxy of overall photosynthetic efficiency). In addition, we analysed the dynamics of special energy fluxes ABS/RC, DIo/RC, TRo/RC, ETo/RC to assess the absorption, dissipation, trapping, and electron transport rates,

respectively, in photosystem II (PS II).

Data analysis was conducted in R (v.4.2.2) using packages 'lme4' and 'emmeans'. The effects of light treatments and clone, and the interaction of both factors on the physiological and morphological characteristics of plantlets were assessed using linear mixed-effects models or generalised linear mixed-effects models applying Poisson or Binomial residual distribution depending on the data type analysed. Model assumptions were evaluated by visual inspection of residual Q–Q plots and residual-versus-fitted plots. Variance components of random effects were estimated, and intraclass correlation coefficients (ICC) were calculated to quantify variation among experimental units. Model explanatory power was assessed using marginal and conditional R^2 values. For variables where significant effect of light treatment appeared, the estimated marginal means were compared using the Tukey's HSD multiple comparison test. Altogether, data from 336 plantlets (56 jars each containing 6 plantlets) cultivated under experimental setup and control conditions were analysed.

Results and Discussion

Random-effect variance (τ00) associated with jar identity was generally low across most physiological and morphological traits and ranged between <0.0005 to 0.1, indicating that environmental variation between culture vessels was minimal. Intraclass correlation (ICC) coefficients ranged between 0.08 and 0.26, suggesting that only a small portion of total variability could be attributed to differences between jars. This indicates that the experimental conditions were relatively homogeneous and most of the observed variation was explained by clone and light treatment, rather than microenvironmental differences between jars. Marginal R^2 values ranged from approximately 0.14 to 0.51 for most variables, indicating moderate explanatory power of the fixed effects (clone identity and light treatment), which is common in biological systems, where quantitative traits are determined by many factors simultaneously (Hill, 2010). Conditional R^2 values were only slightly higher (0.22 to 0.57), suggesting that variation attributable to jar identity was relatively small.

Changes in the R:Fr ratio influenced plant development, as indicated by a significant effect of light treatment on measured variables (Table 2). For some parameters (PI_{ABS}, TRo/RC, ETo/RC, main-to-total shoot length ratio and average internode length), a significant clone × light treatment interaction was observed, indicating clone-specific responses to changes in spectral composition. Overall, clone effects were stronger and more consistent across variables, as reflected by higher χ^2 values compared with light treatment. Genetic differences between clones have previously been shown to strongly influence the proliferation capacity of silver birch plantlets *in vitro* (Ryynänen L. & Ryynänen M., 1986). Accordingly, when optimising micropropagation performance, the clone selection may play a more important role than specific environmental treatments, such as adjustments in the R:Fr ratio.

Table 2

Significance of clone identity, light treatment, and their interaction for physiological and morphological traits based on mixed-effects models displayed as χ^2 values

Variable	Clone	Light treatment	Clone × Light treatment interaction
SPAD	15.26***	51.22***	0.43
Fv/Fm	101.44***	4.15*	2.17
PI_{ABS}	94.77***	0.29	11.56**

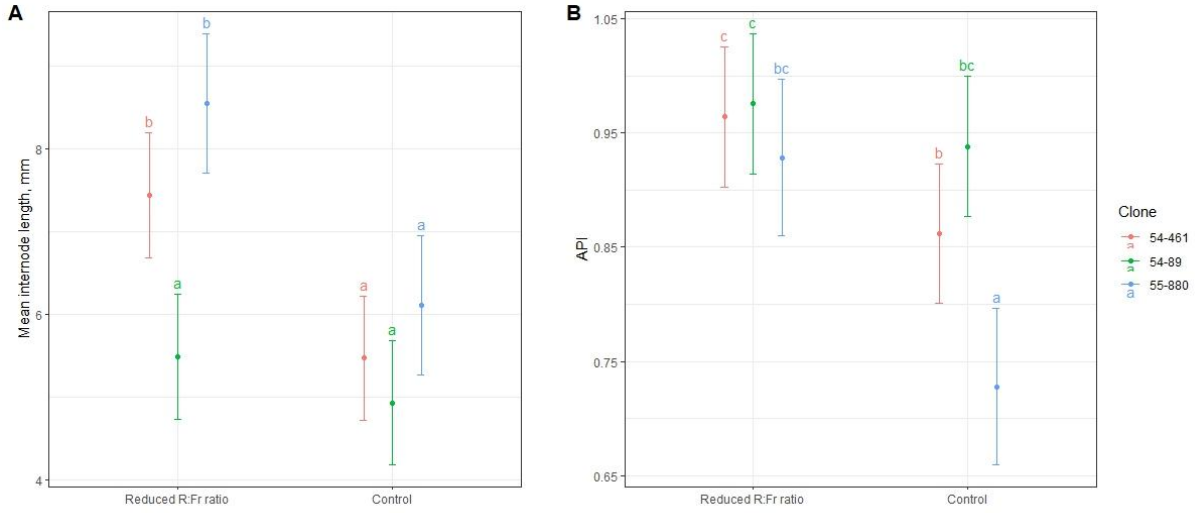
Although the effect of clone was generally stronger, light treatment played an important role in shaping plant morphology. In particular, the R:Fr ratio exerted pronounced effects on morphology compared to physiology, as indicated by a significant effect of light treatment on 6 of 8 morphological variables versus 4 of 7 physiological variables (Table 2). Such decoupling of architectural adjustment from the



photosynthetic performance is characteristic to phytochrome-mediated shade-avoidance responses under low R:Fr conditions (Ballaré & Pierik, 2017; Casal, 2012; Franklin & Whitelam, 2005). Under such conditions, plants respond primarily through elongation and modifications in shoot architecture that improve access to light, while changes in the efficiency of the photosynthetic apparatus are secondary and are maintained within an optimal range (Franklin, 2008; Smith, 2000). Nonetheless, changes in the R:Fr ratio affected morphological traits associated with the growth of the main shoot (main shoot length, mean internode length), the formation of lateral shoots (number of lateral shoots, proportion of plants forming lateral shoots, and the ratio of main to total shoot length), and rooting rate (Table 2), whereas the number of internodes of the main shoot and the multiplication index remained unchanged. Considering that the ratio of main to total shoot length was significantly affected by light treatment, the stability of the multiplication index suggests that the overall growth was not substantially altered but rather redistributed among plant organs. Such observation is consistent with typical shade-avoidance responses where low R:Fr primarily modifies biomass allocation rather than increasing total carbon assimilation (Ballaré & Pierik, 2017; De Wit et al., 2016; Franklin, 2008).

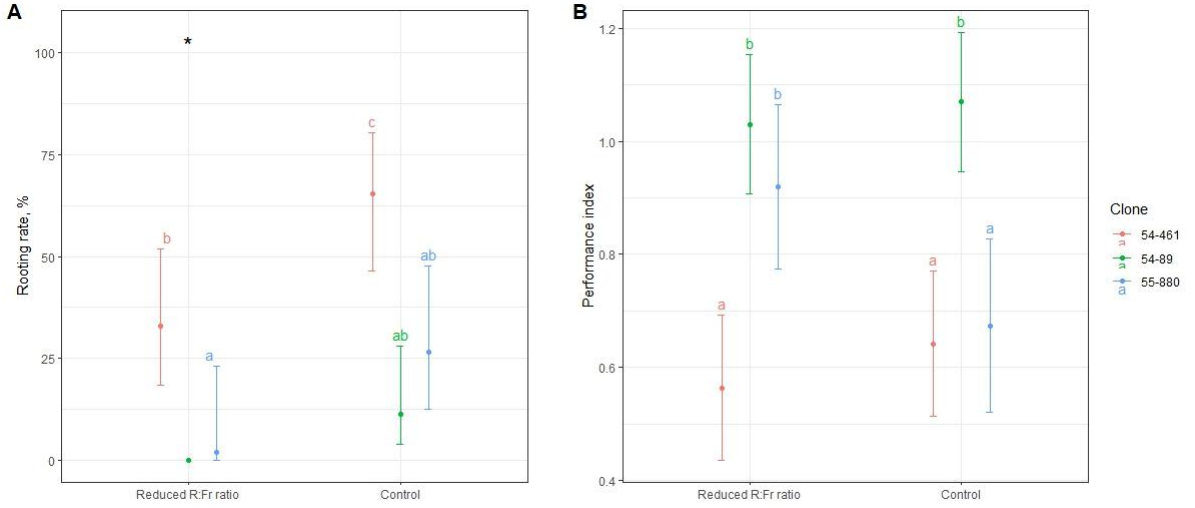
Although the effects were more pronounced for morphological traits, light treatment also influenced chlorophyll content and the functional performance of PSII, as reflected by changes in SPAD values and chlorophyll *a* fluorescence parameters Fv/Fm and PI_{ABS}, as well as in the specific energy fluxes describing electron trapping (TRo/RC) and electron transport (ETo/RC) in PSII reaction centres (Table 2). In contrast, the energy absorption (ABS/RC) and dissipation (DIo/RC) were not affected, suggesting that the applied light conditions did not induce photoinhibitory stress, which is typically associated with increased energy dissipation and reduced PSII efficiency (Kalaji et al., 2012; Maxwell & Johnson, 2000). Changes in chlorophyll content under altered R:Fr ratios are frequently reported in shade environments, where plants adjust pigment composition and leaf optical properties while maintaining relatively stable photosynthetic efficiency (Ballaré & Pierik, 2017; Casal, 2012; Franklin, 2008). However, such responses are not exclusively associated with shade-avoidance signalling and may also reflect photosynthetic acclimation to broader variations in spectral environment, including adjustments in chlorophyll concentration that optimise light-harvesting efficiency under altered light conditions (Demotes-Mainard et al., 2016; Evans & Poorter, 2001; Walters, 2005).

Plantlets cultivated under illumination with reduced R:Fr ratio developed longer main shoots estimated at 36.0 mm (95% Confidence Interval ($CI_{95\%}$): 34.0-37.9 mm) compared to 28.5 mm ($CI_{95\%}$: 26.6-30.5 mm) for the control group, while the elongation occurred on account of longer internodes (Figure 1A), as the internode number remained stable.

Figure 1

Changes of the mean internode length (A) and API (B) of silver birch clones cultivated under illumination with different R:Fr ratios

Such responses are widely observed across plant species and reflect an evolutionary adaptation to canopy shade, where rapid architectural adjustments enable plants to escape unfavourable light environments (Ballaré & Pierik, 2017). At the molecular level, this response is initiated by phytochrome inactivation under low R:Fr conditions, which stabilises phytochrome-interacting-factor (PIF) transcription and promotes auxin transport and gibberellin biosynthesis, ultimately driving stem and internode elongation (Demotes-Mainard et al., 2016; Wang et al., 2022). At the same time, node initiation at the shoot apical meristem is controlled largely by the developmental regulation of leaf initiation rather than



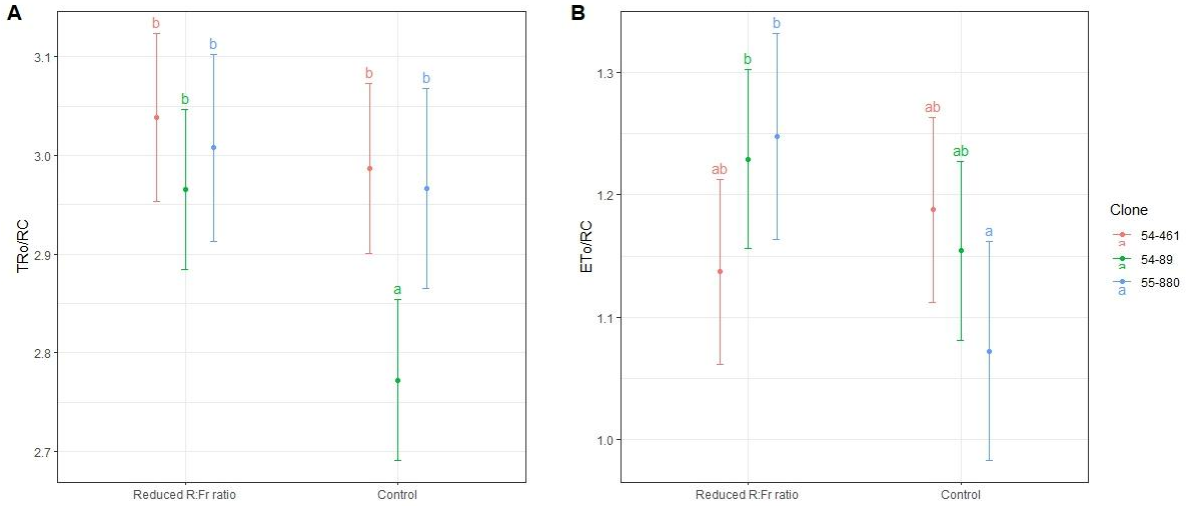
elongation processes, and is therefore less sensitive to changes in spectral quality, including the R:Fr ratio (De Wit et al., 2016).

Despite main shoot length being increased, changes in total shoot length were not observed, indicating that decreased R:Fr ratio did not stimulate overall biomass accumulation but instead induced redistribution of growth resources within the shoot system. Reduced R:Fr ratio stimulated resource allocation from lateral shoots to the main axis, as indicated by reduced lateral branching estimated at 14.5% ($CI_{95\%}$: 8.8-14.5%) versus 40.1% ($CI_{95\%}$: 31.1-49.8%) for the control group, and increased API (Fig. 1B). The mean number of lateral shoots was higher under the control condition, with an estimated value of 0.388 ($CI_{95\%}$: 0.287–0.524), compared with 0.149 ($CI_{95\%}$: 0.089–0.250) under the treatment, indicating a significant reduction in lateral shoot formation. Observed responses represent typical shade-avoidance mechanism regarding biomass allocation within plants (Franklin & Whitelam, 2005), and have been widely reported in herbaceous plants (Casal, 2012; Smith, 2000). From the practical perspective, such a shift towards stronger apical dominance may be beneficial for micropropagation by reducing excessively bushy phenotypes and improving the structural quality of shoots during subculture (Ballaré & Pierik, 2017; Demotes-Mainard et al., 2016; Franklin, 2008). Sustainable changes in biomass allocation should, however, be confirmed over several subcultures to ensure consistency of the response for practical applications.

Considering that Fr enrichment modulates auxin metabolism via phytochrome-mediated signalling, enhanced adventitious rooting could be expected, as demonstrated with the cuttings of watermelon (Wu et al., 2023) and lavender (Muleo et al., 2025), where reduced R:Fr ratios accelerated root initiation and increased root biomass. We observed that the rooting rate of silver birch clones under decreased R:Fr ratio was lower (Figure 2A) compared to the control group. Reduced rooting can result from an excessive reduction in the R:Fr ratio (Sessa et al., 2018). However, because the R:Fr ratio used in this study was moderate, the reduced rooting was likely caused by other factors. This could include the application of cytokinins to the culture medium, which are characterised by their inhibitory effect on rooting (Jing & Strader, 2019). Cytokinins may have also interacted with elevated levels of Fr, as reduced rooting was observed in comparison to the control, where the R:Fr ratio was elevated (Table 1). This, however, remains speculative, and should be tested experimentally to verify.

Figure 2

Changes of rooting rate (A) and Performance index PI_{ABS} (B) of silver birch clones cultivated under illumination with different R:Fr ratios



*Note – no rooting was observed for clone 54-89 cultivated under reduced R:Fr ratio, dispersions were therefore removed to improve graphic representation.

In terms of photosynthetic performance, reduction of the R:Fr induced only minor changes. Exposure to illumination with reduced R:Fr ratio resulted in slightly reduced photosynthetic capacity, as indicated by significantly lower SPAD for the plantlets with estimated value 20.6 ($CI_{95\%}$:19.7-21.4) versus estimate 24.2 ($CI_{95\%}$:23.3-25.0) for the control group. Unlike etiolation, the shade avoidance does not induce complete suppression of chlorophyll accumulation (Demotes-Mainard et al., 2016). Accordingly, photosynthetic capacity is usually maintained with only a slight decrease in performance, allowing plants to sustain carbon assimilation while reallocating resources toward elongation growth (Tan et al., 2022). Reduced R:Fr treatment also resulted in significantly higher Fv/Fm value with 0.809 ($CI_{95\%}$:0.801-0.817) compared to 0.797 ($CI_{95\%}$:0.789-0.805) control group, indicating higher quantum yields in response to the

reduced R:Fr. Nonetheless, both groups remained at the range that is estimated as optimum (Maxwell & Johnson, 2000), suggesting that illumination did not induce photoinhibition for plantlets in both groups. The reduction of R:Fr ratio also resulted in a significantly higher PI_{ABS} for clone 54-89 (Figure 2B), indicating a slight increase of overall photosynthetic efficiency; increased electron trapping in PS II for clone 54-89, as indicated by higher TRo/RC (Figure 3A) and increased electron transport beyond Q_A for clone 55-880, as indicated by higher ETo/RC (Figure 3B). Changes in Performance Index and electron fluxes (TRo/RC and ETo/RC) were, however, clone specific and seemed random, without exhibiting a distinguishable pattern, thus further reinforcing relative stability of photosynthesis under the reduced R:Fr ratio, characteristic to shaded environment (Casal et al., 2014; Franklin, 2008).

Figure 3

Changes of special electron fluxes TRo/RC (A) and ETo/RC (B) for silver birch clones cultivated under illumination with different R:Fr ratios

Conclusions

1. Silver birch clones exhibit typical shade-avoidance responses under the reduced R:Fr environment.
2. Morphological responses of silver birch to the reduced R:Fr ratio are more pronounced than physiological changes.
3. The reduction of R:Fr ratio enhances growth of main axis by reducing resource distribution to lateral shoots, thus improving transplant-ready morphology.
4. Physiology of plantlets adjusted to the reduced R:Fr environment via optimisation of photosynthetic capacity and efficiency, while maintaining the overall stability of photosynthetic performance.
5. The reduced R:Fr ratio has the potential to optimise micropropagation of silver birch.

CASE STUDY OF BIRD'S-FOOT TREFOIL (*LOTUS CORNICULATUS*), WOOD FIBER, PEAT FOR SAND AND GRAVEL QUARRY RECLAMATION

***Viktorija Vendina[1,2], Dagnija Lazdiņa[1]**

Abstract
After sand and gravel extraction, mined areas must be reclaimed. The most common reclamation practice is afforestation; however, the remaining soil after extraction is usually nutrient-poor, dry, unstable, and low in organic matter, making it highly susceptible to erosion. Bird's-foot trefoil (*Lotus corniculatus*), a legume, is a promising species for reclamation. The aim of the study was to evaluate two measures for gravel quarry reclamation: (i) vegetation establishment by sowing *Lotus corniculatus* between tree rows in a gravel quarry (Kapusils, Latvia), and (ii) the effect of wood fiber–peat mulch on tree growth in a nursery (Kalsnava, Latvia) and in the gravel quarry. Two growing seasons after sowing, approximately 14.5% of bird's-foot trefoil plants were classified as large, 30% as medium-sized, and the remaining plants as small. In most cases, root dry mass exceeded aboveground dry mass. The combined application of wood fiber–peat mulch at tree planting spots together with bird's-foot trefoil sown between tree rows may reduce wind erosion while improving soil stability, moisture availability, and nutrient supply for newly planted trees. As a result, this approach can contribute to soil improvement, reduce erosion, provide resources for pollinators, and enhance biodiversity in reclaimed areas.
Keywords: bird's-foot trefoil, biomass, wood fiber, peat, sandy soil recultivation.

Introduction

Sand and gravel are among the most widely extracted construction materials worldwide (Gavriletea, 2017). In Latvia, approximately 3 million m³ of sand and about 2.6 million m³ of sand–gravel are extracted annually (Latvian Environment, Geology and Meteorology Centre, 2025), mainly for concrete production, road construction, and other building activities. However, extraction significantly disturbs the natural landscape, removing vegetation and topsoil and exposing loose sediments (Bradshaw, 2000). After mining operations cease, these disturbed surfaces become highly vulnerable to erosion, particularly during the early stages before reclamation measures stabilize the site (Bendixen et al., 2021). Because exposed sand and gravel have low cohesion, rainfall runoff and wind can easily mobilize and transport sediments, contributing to land degradation and dust pollution (Morgan, 2005).

Various methods are used to control erosion and sedimentation in post-mining areas, including vegetation establishment (Navarro-Ramos et al., 2022), mulch application (Fan et al., 2023), silt fences, sediment ponds (Kincl, 2022), and surface runoff diversion (Martín-Moreno et al., 2016). Among these approaches, vegetation establishment is particularly promising because it provides multiple ecological benefits, including improved soil stability, enhanced biodiversity, habitat creation (Bradshaw, 2000), carbon sequestration (Zhu et al., 2024), and improved soil nitrogen (N) availability through legumes (Junia et al., 2020). One legume species with strong potential for the reclamation of degraded soils is bird's-foot trefoil (*Lotus corniculatus*), which can form stable ground cover while improving soil fertility through biological N fixation (Knežević et al., 2022).

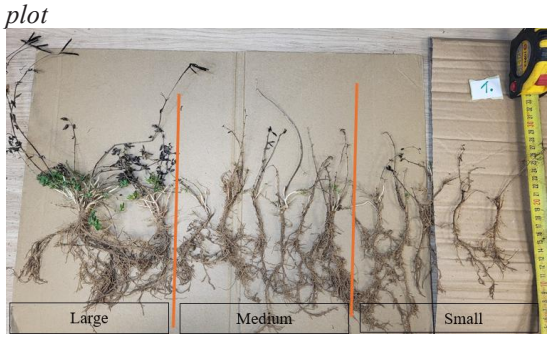
In addition to vegetation establishment, soil amendments may improve conditions for plant, including trees, establishment on nutrient-poor sandy substrates. A mixture of wood fibre and peat may create favorable conditions for the early growth of planted trees because each component provides complementary functions. Peat improves water retention due to its high porosity, which is particularly important during the early establishment stage when seedlings are sensitive to drought stress (Rezanezhad et al., 2016). Wood fiber decomposes more slowly and forms a coarse surface matrix that stabilizes sandy soils by trapping moving particles and reducing surface erosion. Wood-based mulches have also been shown to effectively stabilize soil surfaces during the early stages of vegetation establishment (Girona-García et al., 2022; Neris et al., 2017). Together, these materials may enhance nutrient availability, improve moisture conditions, and stabilize the soil surface, thereby supporting vegetation establishment and reducing erosion in sandy post-mining landscapes.

The aim of the study was to evaluate the suitability of two measures for gravel quarry reclamation (afforestation): (i) the incorporation of bird's-foot trefoil between tree rows in a gravel quarry; and (ii) the effect of wood fiber and peat mix mulching on tree growth, both in the nursery and in the gravel quarry. The specific focus of the study regarding bird's-foot trefoil as a ground cover species was its growth performance, root biomass development, and potential for natural reseeding in nutrient-poor substrates.

Materials and Methods

Bird's-foot trefoil incorporation effect

Bird's-foot trefoil (*Lotus corniculatus*) was sown in the end of May 2024 in 15 cm wide rows at a reclaimed sand–gravel quarry site (Kapusils study site) in Latvia, located approximately 250 km northwest of Riga (57.33136, 25.95272). Total area of study site is 10 ha. In autumn 2025 (after two growing seasons since sowing), biomass samples of bird's-foot trefoil were collected from five sampling plots (area of each



sampling plot 225 cm^2, distance between sampling plots 5 m), and the number of individuals as well as the dry biomass of roots and aboveground parts were determined. Since bird's-foot trefoil was sown in rows and its root system is known to expand spatially, a 15 × 15 cm area within each sampling plot was selected as the representative sampling unit (Figure 1).

Figure 1
The selected 15x15 cm area for collecting bird's-foot trefoil

After excavation, the soil was carefully shaken off and the number of large (>10 cm), medium (5–10 cm), and small (<5 cm) bird's-foot trefoil individuals within the sampling plot was recorded (Figure 2).

Figure 2
Bird's-foot trefoil individuals counted in the sampling plot

The proportion (%) of large, medium, and small individuals was determined for each sampling plot. Root and aboveground biomass were oven-dried at 70 °C to constant mass and weighed. The proportion of root and aboveground biomass in each sampling plot was then calculated.

Soil samples from 0 – 5cm depth (5 replicates) were collected from the bird's-foot trefoil row adjacent to the biomass sampling plot. Control set of soil samples were taken from the unsown soil next to the row. All soil sample analyses were carried out at the laboratory of the Latvian State Forest Research Institute 'Silava'. Soil pH was determined in a water (H_2O) suspension. The concentrations of potassium (K), calcium (Ca), magnesium (Mg), zinc (Zn), iron (Fe), manganese (Mn), phosphorus (P), aluminium (Al), nickel (Ni), copper (Cu), lead (Pb), boron (B), sodium (Na), and sulfur (S) were measured after microwave-assisted digestion using a CEM MARS 6 iWave system (Matthews, USA); elemental analysis was performed with an inductively coupled plasma optical emission spectrometer (ICP-OES; Thermo Fisher Scientific iCAP 7200 Duo, Waltham, USA) following the ISO 11885:2009 standard. Total carbon (TC) and total nitrogen (TN) contents were determined by the dry combustion method using an Elementar El Cube analyzer (Langenselbold, Germany) in accordance with ISO 10694:2006 and ISO 13878:1998, respectively. Carbonate content determined using FOGII Digital Soil Calcimeter, while organic carbon (OC) content calculated as a difference between TC and carbonate content. Statistical analysis was performed using the R software (version4.4.0). To compare the chemical indicators of soil samples collected under bird's foot trefoil with those from the control sites, Welch's two-sample t-test for independent samples was used. Since multiple soil chemical parameters were analyzed simultaneously, the p-values were adjusted using the Benjamini–Hochberg method to control the false discovery rate (Benjamini & Hochberg, 1995). Differences were considered statistically significant at $p < 0.05$.

Wood fiber and peat mix mulching effect

The substrate/mulch formulation was designed with the consideration that adding wood fiber also known as trade mark 'forest gold' (FG) would stimulate the activity of wood-decomposing bacteria, which consume mineral N; therefore, substrates with higher wood fiber content received more mineral N (Table 1). Additional N was added using NPK (12-14-24)+TE (0.5 kg m^{-3} of peat) in all treatments; in substrates containing wood fiber, slow-release N fertilizer containing urea and crotonylidene diurea (CDU) was added.

At the Kapusils study site, individual planting spots were mulched in 2024, applying 0.4 kg of natural wet mulch per planting spot. The height of planted bare-root and container-grown Norway spruce seedlings at the Kapusila study site was determined in 2024.

But in Kalsnava nursery wood fiber and peat mulching (3 t ha^{-1}) effect on spruce growth had been tested in production of Plough+ *Norway spruce* seedlings in 2024. In nursery, the measurement of trees was done after one year. For each type of mulch material, tree height (classified into height groups at 10 cm intervals: 10-20 cm, 20-30 cm, 40-50 cm, 50-60 cm, and 60-70 cm) was measured and the proportion of seedlings within each 'height class' was calculated.

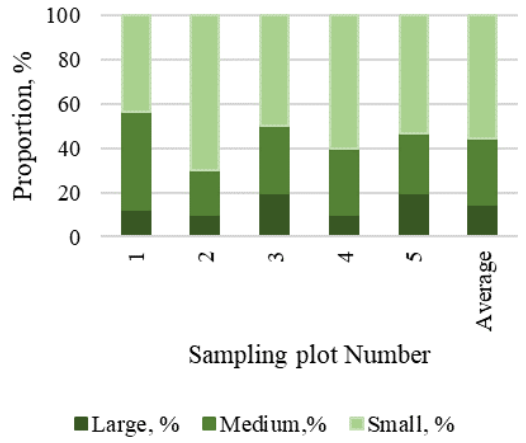
Results and Discussion

Bird's-foot trefoil individuals and biomass

The proportion of large, medium, and small bird's-foot trefoil individuals varied among the five sampling plots (Figure 3). Small individuals represented the largest share in most plots, indicating that a considerable part of the population consisted of less developed plants. On average across all sampling

plots, small individuals constituted the largest proportion of the population 55.4 ± 9%, while medium individuals accounted for 30.1 ± 8% and large individuals for 14.5 ± 5%.

Table 1



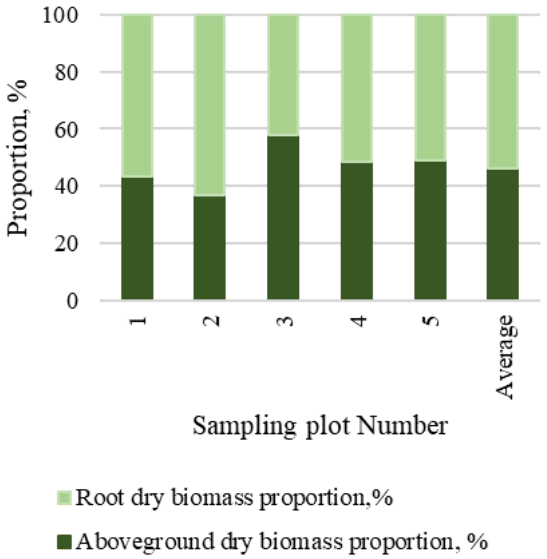
The amount of additional nitrogen fertilizers added to the standard substrate recipe of SIA Pindstrup

Source of nitrogen	Amount of additional nitrogen added, g m^{-3}			
	0% wood fiber (FG)	15% wood fiber (FG)	30% wood fiber (FG)	50% wood fiber (FG)
NO_3 – N	35	35	35	35
NH_4 – N	25	25	25	25
UREA – N	-	2.7	5.40	7.5
CDU Nitrogen	-	25.20	50.40	70

These results indicate that the *L. corniculatus* population at the study site was dominated by smaller, less developed individuals.

Figure 3

Proportion of different size Bird's-foot trefoil individuals in the sampling plots



In the early stages of reclamation, relatively low vegetation height, even within pioneer plant communities, is considered a typical characteristic. During this phase, many plant species allocate a greater proportion of their resources to root development (Boldt et al., 2012) and survival strategies rather than to rapid above-ground growth. Well-developed root systems enable plants to access limited soil moisture and nutrients while simultaneously stabilizing loose substrates like sand and gravel, thereby reducing erosion (Vannoppen et al., 2017).

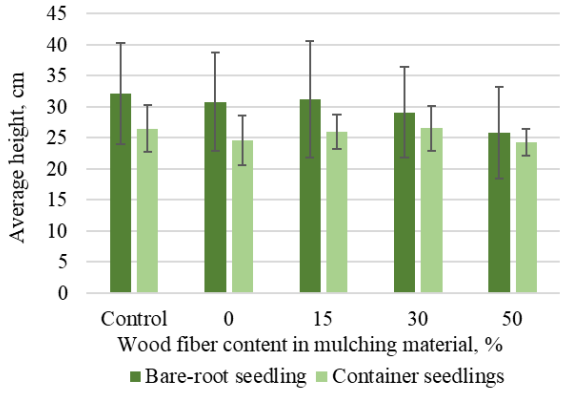
The biomass allocation of bird's-foot trefoil varied among the five sampling plots, with the proportion of aboveground dry biomass ranging from approximately 37% to 58% (1.85…4.05g), while root biomass ranged from about 42% to 63% (1.95…5.68g). The highest proportion of aboveground biomass was observed in sampling plot 3, whereas sampling plot 2 showed a relatively greater allocation of biomass to roots (Figure 4). Differences in biomass allocation among sampling plots may also reflect local variations in microsite conditions such as soil moisture, nutrient availability, or substrate composition. For example, the higher proportion of aboveground biomass observed in sampling plot 3 may indicate more favorable moisture conditions that allowed greater investment in shoot growth. Similar patterns have been reported in other studies of leguminous species, where biomass allocation shifts depending on resource availability and environmental stress (Poorter et al., 2012).

Figure 4

Proportion of bird's-foot trefoil oven dry biomass

Bird's-foot trefoil impact on soil quality

Among the analyzed soil chemical indicators—OC, TC, TN, the C/N ratio, K, Ca, Mg, Zn, Fe, Mn, Ni, Cu, lead Pb, B, Al, Na, S, and P concentrations—no statistically significant differences were found between the control soil and the soil beneath bird's-foot trefoil ($p > 0.05$). This can be explained by the fact that reclamation and the recovery of soil fertility are long-term processes, and measurable improvements in soil chemical properties often require several years or even decades to develop. In the early stages of reclamation, soil systems are still undergoing physical stabilization and biological colonization, while processes such as organic matter accumulation,



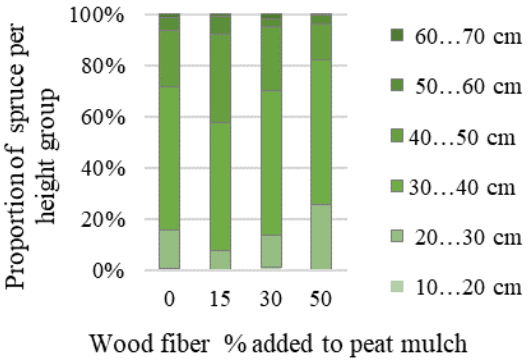
nutrient cycling, and the development of microbial communities are only beginning to establish (Navarro-Ramos et al., 2022; Li et al., 2025). However, significant differences were detected in the content of carbonate carbon (Ccarb.; p = 0.0016) and calcium carbonate ($CaCO_3$; p = 0.0016), less Ccarb. contain noncovered soil what could be result of wind erosion – material accumulation or removing on topsoil.

Tree growth with wood fiber mulch

In the Kapusils sand mining recultivation area, after the first growing season, no visible differences in seedling height were observed among seedlings, regardless of whether the planting spots were mulched or not. Unsignificant shorter seedlings developed in planting spots mulched by material containing 50% of wood fibre (Figure 5).

Figure 5

Average height (cm) of Norway spruce seedlings (bare-root and container-grown) under different wood fiber contents in the mulching material (0%, 15%, 30%, and 50%), compared to the control. Error bars represent standard deviation (SD)



At this stage, the mulch layer had become covered by sand, and the root collars of the planted seedlings were also covered, which may have contributed to their protection against wind erosion.

In experimental planting on sandy soils in Kalsnava nursery, we found that peat+15-30% wood fiber improve seedling quality (Figure 6). Mulching of nursery-ploughed soil bare-root Norway spruce seedlings showed better results when 15 and 30% wood fibre was added to the peat mulch for improving soil organic material content, less higher seedlings with 50/50 peat / wood fiber mulch.

In summary, the current observations suggest that the future combination of localized mulching at planting spots and a living legume cover in inter-rows may be particularly suitable for tree establishment on erosion-prone sandy soils. In such environments, the immediate challenge is often not nutrient limitation alone, but rather the physical instability of the surface substrate, including sand deflation, burial of planting spots, and exposure of the root collar. Vegetation cover is known to reduce wind erosion by increasing surface roughness and decreasing near-surface wind velocity, while mulch-based surface protection can provide an immediate barrier before living cover is fully established (Zhang et al., 2021; Girona-García et al., 2022).

Figure 6

Distribution of Picea abies seedlings among height classes according to the proportion of wood fiber added to peat mulch in a sandy soil field at the Kalsnava nursery

In this context, bird's-foot trefoil can be viewed as a biologically persistent, cumulative erosion-control component. Once established, it is expected to maintain soil cover over time and thereby contribute to longer-term suppression of aeolian sand movement. At the same time, as a perennial legume, it may also contribute N to the system through biological fixation; however, the transfer of legume-derived N to neighboring non-legume plants generally occurs gradually and is often mediated by decomposition of root residues and other belowground pathways rather than by an immediate fertilizer-like effect (Thilakarathna et al., 2016; Reilly et al., 2022).

By contrast, a mulch composed of wood fiber, peatwould be expected to act immediately after planting by physically stabilizing the planting microsite. This is especially relevant under sandy conditions, where the root collar may be either exposed by deflation or buried by wind-blown material. Mulches are widely used to reduce erosion and protect the soil surface during the vulnerable establishment phase, and woody amendments may additionally improve water retention and soil physical conditions in degraded coarse-textured soils (Jourgholami & Etehadi Abari, 2017; Li et al., 2018). Soil physical improvement is particularly important because better aggregation, porosity, and infiltration can moderate moisture stress and improve aeration in sandy substrates (Bronick & Lal, 2005).

The temporal contrast between the effects of living cover and woody mulch is central to the proposed interpretation. Wood-based materials typically have a high C/N ratio and therefore may temporarily immobilize N during decomposition, meaning that their short-term benefit is more likely to be physical than nutritional. Nevertheless, the more slowly decomposing carbon fraction may contribute to

gradual improvement of soil structure and moisture relations (Li et al., 2018; Bronick & Lal, 2005).

Latvian agroforestry studies provide additional support for the ecological logic of combining woody plants with herbaceous intercrops and recycled nutrient sources. In an agroforestry alley cropping experiment established in central Latvia, Rancāne et al. (2014) showed that systems combining hybrid aspen with perennial herbaceous plants on mineral soil could generate positive agronomic and economic outcomes, particularly, where herbaceous crops were used for seed production and organic fertilization treatments were applied. The same study also demonstrated that alley cropping was evaluated not only as a productive land-use option but also as one offering environmental benefits, including soil-protective functions and diversified biological production.

More specifically, Bārdule et al. (2013) reported from a Latvian agroforestry system on loam/sandy soils that wastewater sludge increased hybrid aspen stem length after the first growing season, while wood ash substantially increased seed yield of fodder galega, illustrating that recycled residual materials can influence tree and intercrop components differently. Their study is particularly relevant here because it demonstrates, under Latvian conditions, that wood ash can function as a meaningful nutrient source within mixed tree–herbaceous systems and that perennial intercrops can be successfully maintained between tree rows.

Overall, the proposed combination of wood fibre–peatmulch in the immediate planting spot and bird's-foot trefoil in the inter-rows appears conceptually strong because it aligns short-term and long-term mechanisms of site improvement. The mulch layer is likely to provide immediate physical protection against wind erosion and burial–exposure stress around the root collar, while the legume cover can progressively strengthen biological stabilization of the soil surface. By the time root turnover in the trefoil stand begins to release appreciable quantities of N and C, the root systems of planted trees are likely to be better developed and more capable of exploiting those resources. Thus, from a discussion perspective, the advantage of this combined approach is not that both components act identically, but rather that they act on different time scales and through complementary mechanisms: mulch offers rapid microsite protection, whereas the legume cover offers cumulative ecosystem service delivery through persistent cover, organic matter inputs, and delayed nutrient transfer (Li et al., 2018; Thilakarathna et al., 2016; Bārdule et al., 2013; Bārdulis et al., 2021).

Conclusions

1. Bird's-foot trefoil showed good suitability for the reclamation of sand and gravel mining areas, demonstrating the ability to grow in nutrient-poor conditions.
2. The population of bird's-foot trefoil was dominated by small individuals (55.4%), indicating ongoing establishment and development, while biomass allocation varied among plots but remained relatively balanced between aboveground and root biomass, reflecting adaptation to nutrient-poor soils.
3. The combined use of mulch (wood fiber, peat) at planting spots and bird's-foot trefoil in inter-rows could provide both immediate protection against wind erosion and longer-term improvement of soil stability, moisture conditions, and nutrient availability for newly planted trees.
4. Mulching during production of Plough+ Norway spruce seedlings in nursery showed better results when peat in mulch was supplemented with 15 or 30% wood fiber.
5. After the first growing season, mulching had no significant effect on Norway spruce containerized and bare-root seedlings height in the Kapusils sand mining recultivation area, while sand accumulation over the mulch and root collar provide additional protection to the planted seedlings.

Acknowledgements

Research on the recultivation of the Kapusils sand and gravel mining site was funded by 'Doctoral grants' (agreement No. 1.1.1.8/1/24/I/002), while experiments established with wood fiber and peat mulching materials were supported by the Forest Sector Competence Centre of Latvia (No. 5.1.1.2.i.0/1/22/A/CFLA/007) as part of Pindstrup project P20.

Current experiment is part of InBestSoil (ID 101091099) Light house.

MANUAL PIPETTING: A MULTI-SECTOR STUDY WITH DRY-VERIFICATION TECHNOLOGY (ATMOS-1)

Avo Karus
Estonian University of Life Sciences, Estonia
Corresponding author's email: avo.karus@emu.ee

Abstract
This study evaluated pipetting accuracy, precision, and leakage across six Estonian laboratories—including medical diagnostics, university research, and authority labs—using the Atmos-1 device, an advanced, rapid, and environmentally independent pipette verification tool. The results revealed substantial variability in pipetting performance among the different sectors. Authority and medical laboratories, which operate under strict regulatory frameworks and frequent calibration routines, demonstrated consistently higher accuracy and precision in pipetting. In contrast, university research laboratories exhibited the greatest frequency of unacceptable deviations, primarily due to inconsistent or reactive pipette verification practices. Notably, the smallest volume pipettes (10–20 µl), used mainly in academic settings, were most prone to significant inaccuracies. Leakage issues were common but often resolved by replacing incompatible pipette tips, highlighting the impact of procurement decisions on laboratory performance. In clinical and authority settings, the consequences of pipetting inaccuracies are minimized by the use of automated analysers, whereas in research environments, manual pipetting errors can directly compromise experimental validity and scientific outcomes. These findings underscore the importance of regular pipette maintenance, comprehensive staff training, and careful selection of compatible consumables. Implementing routine pipette verification, particularly in research institutions, and prioritizing quality in procurement strategies can significantly enhance data reliability and overall research quality. The Atmos-1 device proved to be a valuable tool for enabling rapid, user-friendly, and effective pipette assessment, supporting improved laboratory practices across diverse sectors.
Keywords: Atmos-1, pipetting, quality assurance, accuracy, leakage.

Introduction

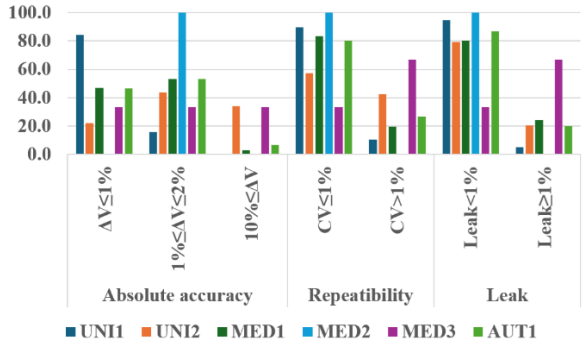
Modern biology and chemistry laboratories, including those for veterinary clinical diagnostics, require precise liquid handling and making micropipette accuracy vital for reproducible results. Accurate and precise measurements begin with correct and proper sampling, labelling and sample transport (delivery) to laboratories. These preanalytical activities will be followed by in-lab work as aliquoting, preparation of necessary solutions, dilutions and finally actual analytical step. For these activities the correctness is often not controlled as it is taken as self-evident. However, this introduces unexpected risks. To mitigate these risks, it is critical to verify measuring devices (such as pipettes) and containers (Blues et al., 2004; Huber, 2025). Traditional pipette calibration methods, gravimetric and photometric methods (Lochner, 1998; Lochner et al., 1996; Pati et al., 2021), are labour-intensive and therefore often outsourced, leaving gaps in regular quality assurance. The Atmos-1 device we used in our study for pipette verification is a gamechanger; it employs advanced pressure sensors and microelectronics to assess precision rapidly, without liquid, in under a minute (Unipix, 2025). Atmos is independent of environmental conditions and can also detect leaks, ensuring optimal pipette performance prior to critical experiments. This is especially important while the user experience may vary or to be insufficient in emerging testing situation (Karus A. & Karus V., 2024), but also in development, validation, and verification of new tests (Carle et al., 2004; Cremonesi et al., 2017; Karus et al., 2017). Problems in volume measurement accuracy and precision can present unexpected obstacles, raising doubts in reliability of scientific findings, adding it to already known challenges (Batista et al., 2007; Guan et al., 2023; Karus A. & Karus V., 2018). The aim of this study was to analyze pipetting practices across different sectors involved in biochemistry and molecular biology using the novel dry measurement technology Atmos-1, to identify potential gaps in pipetting performance, provide evidence of prevalent issues, suggest solutions, and ultimately enhance the quality of pipetting and research data.

Materials and Methods

The single-channel pipette accuracy tester Atmos-1 version 2024-V4.2 was used for measuring pipette accuracy, precision and leakage in six institutions: three medical diagnostics laboratories, research laboratories of two universities and one authority laboratory in Estonia in years 2024 and 2025 on voluntary basis. In every institution, the introductory training was conducted by author on-site for one to three responsible specialists (Yamamoto et al., 2014). Following the training, the Atmos-1 was left in institution for internal evaluation for up to two months. Results were recorded in tester internal memory and downloaded using ReadATMOS software. The selection of pipettes, their volume and number were identified by laboratory personnel according to their everyday use of pipettes and the selection has no impact of authors' influence. Measurements conducted during the initial user training, as well as all measurements with fewer than three repetitions, were excluded from analyses. Results were grouped by user and pipette volume. If leakage was observed, changing pipette tips (to another producer) was recommended and thereafter the testing was subsequently repeated. Accuracy was calculated as relative deviation of the

measured volume from the set value, expressed as a percentage ($\frac{|\bar{x}-V|}{V} \times 100\%$, where $\bar{x}$ – mean of measured pipetting volume and V – set volume on pipette) with good performance defined within 1% and acceptable accuracy as within 2%. Unacceptable failure in accuracy was defined as a deviation greater than 10% and is reported separately. These limits are recommended by manufacturer. Precision was calculated as the coefficient of variation (CV) in percentage. The leakage limit of 1% is set by the instrument software (Unipix, 2025) and was used as fixed recommendation for result acceptance. Institutions are anonymized. Thus, simple descriptive statistics were used to compare different pipette types. Discriminant analysis was performed only at the highest level of generalization to evaluate differences in pipetting quality between user groups (research, medical diagnostics and authority/control laboratories). Because the number of studied pipettes differed across these groups, the Tukey-Kramer test was applied to accommodate the unequal sample sizes, as there were sufficient measurements available (Tukey, 1949; Kramer, 1956). As the ATMOS1 pipetting accuracy tester is indicated for controlling the pipettes in-between required calibration intervals, we did not limit and did not record the measurements done with pipettes recently arrived from regulated periodic calibrations.

Results and Discussion



There are no earlier publications available about real-laboratory situation usage of no-liquid pipette controlling devices of ATMOS-1 or analogues. The introductory training was essential for ensuring an understanding of the basics of techniques, tips and tricks, and best practices required to obtain comparable and reliable results. Data recorded in Atmos-1 memory revealed the diversity of the pipettes in use across institutions. Table 1 provides a summary of pipettes in use in the participating laboratories. The number of other pipette sizes (300 µl and 50 µl) was insufficient for meaningful summary and thus are not shown. Study results demonstrate substantial variation in the accuracy of analysed pipettes. The number of pipettes decreased with smaller volume sizes, and it is notable that smallest volume pipets were used only in university laboratories. Pipette performance data were also analysed on the institutional level and are presented in Figure 1 and summarized in Table 2. The mean deviation values differed across the three institutional groups ($n_1 = 91$, $n_2 = 75$, $n_3 = 15$). A one-way analysis of variance (ANOVA) indicated a statistically significant overall effect of laboratory group on the measured variable ($p < 0.01$). Post hoc pairwise comparisons were performed using the Tukey–Kramer test to account for unequal sample sizes. The Tukey–Kramer analysis demonstrated that all pairwise differences between all groups were statistically significant. Specifically, UNI sector labs differed significantly from MED (medical diagnostic laboratories) ($p < 0.01$) and AUT (authority laboratory) ($p < 0.01$), while MED also differed significantly from AUT ($p < 0.01$). These results indicate that all groups are significantly distinct from one another. Superior pipette performance, and particularly accuracy, in authority and medical laboratories likely reflects regulated testing environments, where pipettes are routinely controlled and calibrated annually or semi-annually according to established rules. In two participated medical laboratories the verification is done locally by gravimetric method. In authority and one medical laboratory, calibration and verification are conducted by certified service providers. In academic (university research) laboratories, pipette calibration and verification are generally not regulated on university level. Practices vary by institute or laboratory, and verification is often only performed when there are reasonable doubts about accuracy.

Table 1

Pipette accuracies and precisions among different pipette sizes (absolute numbers)

		Absolute accuracy			Repeatability (precision)		Leak	
V (µl)	n	ΔV≤1%	1%≤ΔV≤2%	10%≤ΔV	CV ≤ 1 %	CV > 1%	Leak < 1 %	Leak ≥ 1%
1000	66	**39**	24	3	**48**	18	47	19
200	56	19	29	8	42	14	41	15
100	22	9	11	2	17	5	21	2
20	20	5	13	2	16	4	20	**0**
10	17	0	5	**12**	7	10	17	**0**
Total	181	72	82	27	130	51	146	36

Figure 1
Accuracy, repeatability and leakage rate data of pipettes in different institutions

It is also important to note that absolute accuracy deviations have a lower impact in medical and authority laboratories because manual pipetting is mainly limited to sample transfer and aliquoting. Analytical measurements are largely performed with fully automated analysers, reducing the risk of generating erroneous results; the primary concern is obtaining invalid results due to insufficient sample volume (AlShahrany & Ahmed, 2025). In contrast, in research laboratories, pipetting errors can have a greater effect, as deviation in pipetted volume may introduce systematic error. However, bigger volume pipettes tend to expose better accuracy (Lochner et al., 1996). Failures in precision (reproducibility) increase result bias, which can undermine scientific findings, especially when small differences in measured biological values are significant.

Leakage in pipettes can result from a lack of hermeticity, but is most often caused by incompatibility between the pipette and pipette tips (Art et al., 2016; Huber, 2025). Leakage problems were frequently resolved (but not always, with at least six known unresolved cases) by replacing pipette tips as already decades ago was demonstrated by Joyce & Tyler (1973).

This common issue may be partly due to purchasing practices that prioritize price, resulting in suboptimal compatibility between pipettes and tips.

Table 2
Accuracies and precisions of pipettes in different laboratory sectors (research, medical, and authority laboratories) (%)

		Absolute accuracy			Repeatability (precision)		Leak	
Sector	n	ΔV≤1%	1% ≤ΔV≤2%	10%≤ΔV	CV ≤ 1 %	CV > 1%	Leak < 1 %	Leak ≥ 1%
UNI	92	35.2	38.5	**26.4**	64.8	**35.2**	83.5	16.5
MED	74	44.0	52.0	**4.0**	78.7	21.3	76.0	25.3
AUT	15	**46.7**	**53.3**	**0.0**	80.0	20.0	86.7	**13.3**

Conclusions

1. Atmos-1 proved as reliable and easy-to-use pipette accuracy tester in all types of laboratories.
2. There is a substantial variation in pipette accuracy across sectors. Pipette accuracy and precision varied widely between laboratories, with university research labs showing the highest rates of unacceptable deviations and medical/authority labs demonstrating better accuracy and precision.
3. Authority and medical laboratories, which follow regular calibration and verification protocols, consistently maintained pipette accuracy within acceptable limits, highlighting the importance of routine, regulated quality control.
4. The smallest volume pipettes (10–20 µl), predominantly used in university labs, had the highest rates of unacceptable deviations, emphasizing the need for special attention to small-volume pipetting.
5. Pipette leakage is commonly due to tip incompatibility. Most leakage issues were resolved by switching to compatible pipette tips, suggesting that procurement practices focusing solely on cost can undermine pipetting reliability through poor tip compatibility.

Abstract
Pseudomonas aeruginosa and *Staphylococcus aureus* are opportunistic pathogens capable of forming biofilms that exhibit increased tolerance to antimicrobial interventions. Lactic acid bacteria and their metabolites have therefore attracted interest as potential sources of alternative antimicrobial compounds. This study compared the concentration-dependent antibacterial and biofilm-inhibitory effects of *Lactobacillus helveticus* cell-free supernatant (CFS) and a heat-inactivated, non-filtered supernatant (NFS) against *P. aeruginosa* ATCC 27853 and *S. aureus* ATCC 25923 using a microtiter plate model. Planktonic growth, biofilm formation, and minimum bactericidal concentration (MBC) were evaluated, together with acidified, neutralised, and medium controls. Both CFS and NFS showed strong concentration-dependent activity, with an MBC of 12.5 %. At concentrations of 12.5-50.0 %, both preparations nearly completely inhibited planktonic growth and biofilm formation. At 6.25 %, activity was lower and more variable. CFS inhibited *P. aeruginosa* planktonic growth more strongly than NFS, whereas both preparations showed similar activity against *S. aureus*. Both preparations also inhibited biofilm formation at 6.25 %. In the *S. aureus* assays, neutralisation eliminated planktonic growth inhibition, whereas NFS retained a more pronounced biofilm-inhibitory effect than neutralised CFS. Overall, the results demonstrate target and condition-dependent differences between CFS and NFS and suggest that, although acidity contributes substantially to the activity of both preparations, additional pH-independent factors may me involved, particularly in the biofilm-inhibitory activity retained by NFS after neutralisation.
Keywords: crystal violet assay, lactic acid bacteria, postbiotics, *Pseudomonas aeruginosa* ATCC 27853, *Staphylococcus aureus* ATCC 25923.

Introduction

Pseudomonas aeruginosa and *Staphylococcus aureus* are opportunistic pathogens capable of growing either as free-living planktonic cells or within structured biofilm communities. These physiological states differ substantially in their susceptibility to antimicrobial interventions, with biofilm-associated cells generally exhibiting increased tolerance to antimicrobial agents and environmental stressors. Biofilm formation therefore represents a significant challenge to public health (Ciofu et al., 2022), animal health (Howden et al., 2023), food safety, and the hygienic maintenance of food-processing environments and equipment (Elbehiry & Marzouk, 2026). Bacteria embedded within biofilms exhibit increased tolerance to cleaning and sanitation procedures, disinfectants, antimicrobial agents and adverse environmental conditions, which contributes to their persistence on biotic and abiotic surfaces and makes established biofilms difficult to eradicate (Ban-Cucerzan et al., 2025). Consequently, considerable attention has been directed toward the development of alternative and complementary approaches for preventing biofilm formation and controlling established biofilms (Elbehiry & Alajaji, 2026).

Lactic acid bacteria (LAB), including *Lactobacillus helveticus*, produce a broad range of extracellular metabolites and bioactive compounds that may exert antimicrobial and antibiofilm effects (Erdinc & Cufaoglu, 2026). Cell-free supernatants derived from LAB have been widely investigated as sources of antimicrobial activity, which may be associated with organic acids, hydrogen peroxide, peptides, and other secreted metabolites (Erdinc & Cufaoglu, 2026; Khani et al., 2024). However, less is known about whether non-filtered preparations containing potentially retained inactivated bacterial cells, cellular or subcellular material contribute to inhibition beyond the effect of soluble extracellular compounds alone (Loforte et al., 2025). This distinction is particularly relevant in the context of postbiotic research. According to the current consensus definition, postbiotics comprise preparations of inanimate microorganisms and/or their components, with or without microbial metabolites that confer a health benefit on the host (Salminen et al., 2021). Although antimicrobial activity in vitro does not by itself establish a preparation as a postbiotic, comparison of cell-free and heat-inactivated non-filtered preparations may help clarify whether components retained in the non-filtered fraction contribute to antibacterial and biofilm-inhibitory activity. Beyond that associated with soluble extracellular compounds. Such comparisons may therefore provide indirect evidence of the contribution of retained cellular, subcellular, or particulate material, although these components must be characterized directly before their role can be established. Therefore, the present study aimed to comparatively evaluate the concentration-dependent effects of *L. helveticus* cell-free supernatant and heat-inactivated, non-filtered preparation on the planktonic growth and biofilm formation of *Pseudomonas aeruginosa* ATCC 27853 and *Staphylococcus aureus* ATCC 25923 using a microtiter plate model. By directly comparing these preparations, the study sought to determine whether the non-filtered, heat-

treated preparation exhibited inhibitory effects that differed from those of the cell-free supernatant and whether such differences could indicate a contribution of components retained during the different preparation procedures.

Materials and Methods

The capacity of the supernatants to inhibit planktonic growth and biofilm formation was evaluated using a microtiter plate assay.

Preparation of supernatants

A commercially available freeze-dried culture of *Lactobacillus helveticus* THT 031102 (THT s.a., Belgium) was used to prepare the supernatants. Initially, 0.1 g of the lyophilized culture was inoculated into 45 mL of De Man, Rogosa, and Sharpe (MRS) broth (Oxoid, UK) and cultured at 37 °C with shaking at 150 rpm for 24 h. After incubation, the cultures were washed twice with deionized water and re-inoculated into fresh MRS broth at a 1:10 dilution. To prepare the supernatants, the cultures were then incubated at 37 °C at 150 rpm for 42 h.

Viable bacterial count of the *L. helveticus* 42 h old culture was determined by the microdrop plate counting technique described by Naghili et al. (2013). Serial dilutions ranging from 10^{-4} to 10^{-11} were plated on MRS agar and incubated aerobically at 37 °C for 48 h, yielding a bacterial count corresponding to an initial concentration of 7.5 x 10^7 CFU mL^{-1}.

Two types of supernatants were prepared: heat-inactivated, non-filtered supernatant (NFS) and cell-free supernatant (CFS). Initially, the *L. helveticus* culture was centrifuged (4 °C at 4,000 rpm, 10 min), and the supernatant was collected. To prepare NFS, the supernatant was heated in a water bath at 85 °C for 25 min and subsequently cooled to room temperature. To prepare CFS, the supernatant was filtered using a 0.22 µm syringe filter (Avantor, USA). Samples were stored at −30 °C until use.

The absence of viable microorganisms in the supernatants was confirmed by streaking the samples onto Columbia blood agar (Liofilchem, Italy) and MRS.

Preparation of controls

To prepare neutralised supernatants and pH-matched controls, the pH was adjusted using 1 *M* sodium hydroxide (Honeywell Specialty Chemicals Seelze GmbH, Germany), acetic acid (Carl Roth GmbH, Germany), and 1 *M* hydrochloric acid (HCl) (Honeywell Specialty Chemicals Seelze GmbH, Germany). Three types of MRS controls were used: MRS adjusted to pH 3.8 with hydrochloric acid (Control 1), MRS adjusted to pH 3.8 with acetic acid adjusted (Control 2), and MRS adjusted to pH 7.3 with sodium hydroxide (Control 3). The control conditions were assessed only in the *S. aureus* experiments and were not included in the *P. aeruginosa* assays.

Bacterial strains and preparation of preculture

The bacterial strains used in this study were *Pseudomonas aeruginosa* ATCC 27853 and *Staphylococcus aureus* ATCC 25923 (Microbiologics, USA). The cultures were stored in glycerol stock at −80 °C until use.

To evaluate the supernatant's potential to inhibit planktonic bacterial growth and to determine the minimum bactericidal concentration (MBC), firstly, *S. aureus* and *P. aeruginosa* stock cultures were inoculated onto tryptic soy agar (TSA) and incubated aerobically at 37 °C for 18 h prior to the experiment. The preculture was then prepared as follows: Two to three morphologically similar colonies were inoculated into five mL of broth—here and throughout the text, Luria-Bertani (LB) broth (LB) (Liofilchem, Italy) was used for the cultivation and dilutions of *P. aeruginosa*, and Tryptone soya broth (Oxoid, UK), supplemented with 1 % glucose (D-Glucose anhydrous, Fisher Chemical, Germany), was used for *S. aureus* (TSBG). The broth was incubated at 200 rpm for 2 to 4 hours to achieve a turbid suspension with an OD_{620} of 0.3 to 0.6, as measured with a HiPo microplate photometer (Biosan, Latvia). The bacterial count (colony forming units (CFU) mL^{-1}) in the preculture was determined by inoculating a $1:10^4$–$1:10^7$ dilution as drops onto TSA in five replicates, followed by incubation at 37 °C for 18 h. Following incubation, the *P. aeruginosa* and *S. aureus* precultures contained 2.75×10^8 CFU mL^{-1} and 2.01×10^8 CFU mL^{-1}, respectively.

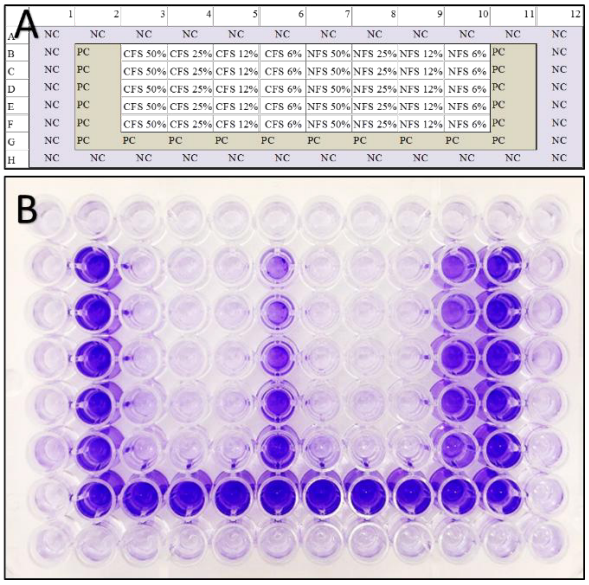
Preparation of working plates

Frozen supernatants were thawed at room temperature before preparation of the working plates, and their pH was measured prior to use. Both samples had a pH 3.8. The supernatants were diluted with LB/TSBG broth to obtain concentrations of 50.0 %, 25.0 %, 12.5 %, and 6.25 %. Then 180 µL of each concentration was dispensed into 96-well polystyrene flat-bottom microtiter plates (Nunc, Thermo Fisher Scientific, Denmark) in five technical replicates.

The resulting preculture was diluted with fresh broth in a 1:10 ratio and 20 µL was added to each test well. As a result, the bacterial concentration in the test wells was approximately 10^6 CFU mL^{-1}. Similarly, a negative control (200 µL of sterile LB/TSBG broth) and a positive control (180 µL of LB/TSBG broth and 20 µL of bacterial culture) were added to the microplate. The plates were incubated at 37 °C, 200 rpm for 18 h. The experimental plate layout is illustrated in Figure 1.

Determination of antimicrobial activity

After an 18-hour incubation period, the plates were first visually inspected for the presence of clear wells, and subsequently the turbidity of the wells (OD at 620 nm) was measured to determine at which concentrations the supernatants inhibit bacterial growth.



To verify the bactericidal activity of the supernatants, the MBC assay was performed according to guidelines established by the National Committee for Clinical Laboratory Standards (NCCLS, 1999). 10 µL aliquots from clear wells in three replicates were transferred to a microtiter plate and serially diluted $1:10^1$–$1:10^7$ with 90 µL of sterile broth. Each dilution was inoculated onto TSA using the spot-plating method and incubated at 37 °C for 18–24 h. Following incubation, growth on TSA was assessed, and the lowest concentration of the supernatants that achieved a 99.9 % CFU reduction of the initial inoculum of the planktonic culture was recorded as the MBC (Pankey & Sabath, 2004).

Determination of antibiofilm activity

The capacity of supernatants to inhibit biofilm formation was assessed using a crystal violet assay adapted from the methodological recommendations of Stepanović et al. (2007).

Figure 1

Microtiter plate layout (A) and assay after staining with crystal violet (B)

NC – negative control; PC – positive control; CFS – cell-free supernatant; NFS – non-filtered supernatant; supernatant concentration is indicated as a percentage (%) of the total well volume.

After plate incubation, the planktonic suspension was decanted into a discard container by flicking. The plate was washed twice with 200 µL per well of sterile 0.9 % NaCl using a multichannel pipette. Following every washing step, the wells were emptied by flicking the plate. After washing, the remaining biofilms were fixed with 200 µL per well of methanol for 15 min at room temperature, under static conditions. Following fixation, the microtiter plate was emptied by flicking and left to air-dry for 15-20 min until fully dry. The plate was stained with 190 µL of 0.1 % v/v Crystal violet (Thermo Fisher Scientific, Belgium) for 15 min at room temperature, under static conditions. After staining, the plates were washed twice with 200 µL of deionized water per well using a multichannel pipette, then left to air-dry for 5 min in a laminar flow hood. The stain was solubilized with 200 µL per well of 96 % ethanol for 30 min at room temperature under static conditions. The absorbance was measured at 570 nm using HiPo microplate photometer (Biosan, Latvia).

An interpretation of biofilm forming inhibition were performed according to the Falqueto et al. (2026). Absorbance values were corrected for background by subtracting the corresponding negative control values. Biofilm inhibition was then calculated relative to the untreated positive control according to Equation 1.

$$Biofilm\ inhibition\ (\%) = \left(1 - \frac{OD_t}{OD_c}\right) * 100 \qquad (1)$$

where OD_t represents the background-corrected OD of the treated culture and OD_c represents the background-corrected OD of the untreated positive control.

The methodological description was prepared with consideration of the minimum information guidelines proposed by Allkja et al. (2019), where applicable.

Statistical assessment and data presentation

A single supernatant preparation was tested in three independent experimental runs. For each run, bacterial cultures and microplates were prepared independently, and each sample was tested in at least five technical replicate wells. For each plate, planktonic growth inhibition and biofilm inhibition were calculated after correction for the background absorbance of the positive (bacteria without supernatants) and negative control (sterile medium). Inhibition was expressed as a percentage (%), and plate-specific mean values were calculated from the technical replicates. Values obtained from independent experiments were combined and are presented as mean ± standard deviation (SD). Planktonic growth inhibition and biofilm formation inhibition were analysed separately. Differences between selected experimental groups were assessed using Welch's independent-samples t-test, with p-values adjusted for multiple comparisons using the Holm method within each supernatant concentration. Additionally, differences between formulations across concentrations were assessed using a linear mixed model with formulation, concentration, bacterial species, and their interaction included as fixed effects. Pairwise comparisons of estimated marginal means were performed with Bonferroni adjustment for multiple comparisons. Statistical significance was set at $p < 0.05$. Figures were created using Microsoft Excel 2013 (Microsoft Corporation, USA). The statistical analyses were performed using IBM SPSS Statistics, version 32.0.0.0 (134) (IBM Corp., USA).

Results and Discussion

Planktonic growth inhibition and MBC

Both *L. helveticus* supernatant preparations showed

strong concentration-dependent antibacterial activity against the tested bacterial strains. The minimum bactericidal concentration (MBC) of both cell-free supernatant (CFS) and heat-inactivated, non-filtered supernatant (NFS) was 12.5 %, indicating a bactericidal effect at this concentration, with a reduction in viable bacterial counts of more than 99.9 % (Table 1).

Three types of controls were included to support interpretation of the antibacterial and antibiofilm effects of the *L. helveticus* supernatants. MRS medium acidified with HCl (Control 1) served primarily as a pH control and was used to assess whether lowering the pH alone was sufficient to reproduce the antimicrobial effect of the supernatants. Although lactic acid is the predominant organic acid produced by *L. helveticus*, MRS supplemented with acetic acid was used as a weak organic acid control (Control 2) to distinguish the effect of low pH from additional weak-acid-specific antimicrobial effects. Organic acids are considered important contributors to the antimicrobial activity of LAB supernatants, together with bacteriocins, hydrogen peroxide, biosurfactants, and other bioactive metabolites (Gong et al., 2026). MRS adjusted to pH 7.3 (Control 3) served as a neutral medium control to determine whether the culture medium itself contributed to inhibition under non-acidic conditions. This control was particularly relevant because the *L. helveticus* supernatants were obtained after cultivation in MRS.

Table 1

Minimum bactericidal concentration (MBC), % (v/v)

pH condition	Supernatant / control	*P. aeruginosa MBC, %*	*S. aureus MBC, %*
Native pH	Cell-free supernatant (CFS)	12.5	12.5
	Non-filtered supernatant (NFS)	12.5	12.5
Acidic controls	MRS + HCl acid (Control 1)	ND	50.0
	MRS + acetic acid (Control 2)	ND	≤ 6.25
Neutralised controls	MRS + NaOH (Control 3)	NA	NA
	CFS and NFS + NaOH	NA	NA

ND - Not determined; NA - Not applicable.

The acidic controls differed markedly in their antibacterial activity. MRS supplemented with acetic acid showed particularly strong bactericidal activity, with an MBC of ≤ 6.25 %, whereas the MBC of HCl-acidified MRS was substantially higher (50 %) and exceeded that of both CFS and NFS. In contrast, MRS adjusted to pH 7.3 did not inhibit planktonic growth of *S. aureus* (Table 2). These observations indicate that extracellular acidification alone was insufficient to account for the activity of the supernatants and also demonstrate that the antimicrobial effects of weak organic acids cannot be considered equivalent to those of a strong inorganic acid at low pH.

Table 2

The inhibition (%) of planktonic growth of S. aureus ATCC 25923

Controls and supernatants	Sample code	Concentration of controls and supernatants, %			
		50	25	12.5	6.25
Native cell-free supernatant (CFS), pH 3.8	A	97.0±0.2 ^{BCEF}	98.1±0.2	97.6±1.9 ^{CE}	46.5±0.6 ^{CEF}
Native non-filtered, heat-inactivated supernatant (NFS), pH 3.8	B	94.8±0.5 ^{ADEF}	97.3±0.4 ^{D}	96.7±1.1 ^{DE}	46.0±3.6 ^{DEF}
Neutralised cell-free supernatant (CFS-N), pH 7.3	C	-39.9±0.7 ^{AG}	-43.3±3.5 ^{G}	-0.1±1.4 ^{AG}	-9.3±3.2 ^{AG}
Neutralised non-filtered, heat-inactivated supernatant (NFS-N), pH 7.3	D	-69.9±7.58 ^{B}	-82.8±6.94 ^{B}	-93.5±2.11 ^{B}	-55.0±3.21 ^{BG}
MRS + HCl acid, pH 3.8 (Control 1)	E	82.6±0.3 ^{AB}	37.5±16.9	-16.6±7.0 ^{AB}	-6.6±3.4 ^{AB}
MRS + acetic acid, pH 3.8 (Control 2)	F	74.7±3.2 ^{AB}	85.8±2.1 ^{B}	63.0±45.6	88.7±0.9 ^{AB}
Neutralised MRS, pH 7.3 (Control 3)	G	-60.9±10.8 ^{C}	-76.3±11.6 ^{C}	-91.0±8.7 ^{C}	-79.7±9.1 ^{CD}

Values are presented as mean ±SD. Superscript capital letters indicate the supernatants from which the corresponding value differed significantly in predefined pairwise comparisons (Welch's tests with Holm adjustment, adjusted $p<0.05$). Comparisons were performed separately within each concentration. The predefined comparisons were A vs B, A vs C, B vs D, A vs E, B vs F, C vs G, and D vs G.

The difference is consistent with the distinct antimicrobial mechanisms of weak organic acids. Undissociated acetic acid crosses bacterial membranes and dissociates within the cytoplasm, disrupting intracellular pH and cellular homeostasis to exert antibacterial and antibiofilm activity (Feng et al., 2022). HCl, in contrast, primarily imposes extracellular acidification and proton stress. Consequently, MRS supplemented with acetic acid showed greater antimicrobial activity then HCl-acidified MRS, consistent with the additional weak-acid-specific effects described for organic acids (Yoon et al., 2024).

Despite the strong activity of the acetic acid control at the lowest concentrations, both CFS and NFS produced near-complete inhibition, whereas their activity became less pronounced and more variable at 6.25 %. Thus, the antibacterial effect of the supernatants was clearly concentration dependent.

Neutralisation further showed that acidic conditions were important for inhibiting planktonic growth. After neutralisation, both CFS and NFS no longer showed detectable antimicrobial activity against planktonic *S. aureus*. Therefore, an MBC could not be determined for the neutralised preparations within the tested concentration range.

These findings support an important contribution of low pH and/or pH-dependent antimicrobial metabolites to the activity of the native supernatants. However, the loss of detectable planktonic growth inhibition after neutralisation does not necessarily imply complete loss of biological activity, as LAB supernatants may contain additional bioactive compounds whose effects are not directly reflected by planktonic growth measurements (Ibrahim et al., 2021).

At concentrations of 25-50 %, CFS and NFS showed similarly strong antibacterial effects against *S. aureus* (Table 2) and *P. aeruginosa* (Table 3) planktonic growth. Differences became more apparent at the lowest tested concentration of 6.25 %, which was below the determined MBC. At this concentration, CFS inhibited planktonic growth of *P. aeruginosa* by 64.0±5.8 %, whereas NFS showed little or no mean inhibitory effect. Pairwise comparison confirmed significantly greater inhibition by CFS than by NFS, with a mean difference of 67.482 percentage points ($p < 0.001$; 95% Cl 63.577-71.387).

Table 3

The inhibition of planktonic growth and biofilm formation of P. aeruginosa ATCC 27853

Controls and supernatants	Planktonic growth inhibition				Biofilm formation inhibition			
	Concentration of controls and supernatants, %							
	50	25	12.5	6.25	50	25	12.5	6.25
Native cell-free supernatant (CFS), pH 3.8	98.0±0.0 ^{B}	98.9±0.2 ^{B}	99.8±0.2	64.0±5.8 ^{B}	97.8±0.4	98.2±0.7	98.8±0.4	75.2±14.3
Native non-filtered, heat-inactivated supernatant (NFS), pH 3.8	96.8±0.4 ^{A}	97.3±0.4 ^{A}	99.4±0.5	-3.3±6.0 ^{A}	97.2±0.6	98.3±0.2	98.9±0.4	56.2±34.7

Values are presented as mean ±SD. Superscript capital letters indicate the formulation from which the corresponding value differed significantly according to Welch's independent-samples t-test ($p<0.05$). Comparisons were performed separately within each concentration.

In contrast, inhibition of *S. aureus* remained similar for the two preparations, reaching 46.5±0.6 % for CFS and 46.0±3.6 % for NFS (Table 2).

At 6.25 %, differences between CFS and NFS against *P. aeruginosa* became more apparent, likely because the overall antibacterial effect was weaker at this concentration. The greater activity of CFS may indicate that heat treatment affected one or more components contributing to growth inhibition. Heat treatment has been reported to reduce the antimicrobial activity of some LAB-derived cell-free supernatants against planktonically growing bacteria, suggesting a contribution of heat-sensitive compounds (Singh et al., 2025). However, this effect is not universal, as LAB-derived antimicrobial components differ in thermal stability and the antimicrobial activity of cell-free supernatants may either decrease following heat treatment (Singh et al., 2025) or remain largely preserved (Scillato et al., 2021). The similar activity of CFS and NFS against *S. aureus* at 6.25 % further suggests that the consequences of heat treatment may depend on the target bacterial species.

Inhibition of biofilm formation

At concentrations of 12.5-50.0 %, both *L. helveticus* preparations inhibited planktonic growth by approximately 94.8 % to 100.0 % and concomitantly reduced biofilm formation by approximately 95.7-98.9 % in both bacterial strains. Because bacterial growth and viability were already strongly suppressed at these concentrations, the reduction in biofilm biomass cannot be interpreted as a specific, standalone antibiofilm effect.

At the lowest tested concentrations of 6.25 %, which was below the determined MBC, the response was

different. At this concentration, inhibition of planktonic growth was substantially lower than at concentrations of 12.5 % and above, whereas considerable inhibition of biofilm formation was still observed. CFS and NFS reduced *P. aeruginosa* biofilm formation by 75.2±14.3 % and 56.2±34.7 %, respectively (Table 3). The difference between CFS and NFS was statistically significant for *P. aeruginosa* (mean difference = 19.01 percentage points, p = 0.016, 95 % Cl 3.875-34.147), indicating a stronger antibiofilm effect of CFS at this concentration. In contrast, *S. aureus* biofilm formation was reduced by 64.6±6.5 and 63.8±3.9 % by CFS and NFS, respectively (Table 4), with no significant difference between the two supernatants (mean difference = 0.784 percentage points, p = 0.916). At 6.25 %, the response of *P. aeruginosa* was more variable than that of *S. aureus*, particularly for NFS, indicating a more heterogeneous effect below the MBC.

Thus, although substantial inhibition of biofilm formation was retained at 6.25 % despite lower inhibition of planktonic growth than at concentrations at or above the MBC, the effect was species – and supernatant-dependent. In particular, the significantly greater inhibition of *P. aeruginosa* biofilm formation by CFS compared with NFS suggest that the antibiofilm activity observed below the MBC may not explained solely by the overall inhibition of bacterial growth.

Table 4

The inhibition (%) of biofilm formation of S. aureus ATCC 25923

Controls and supernatants	Sample code	Concentration of controls and supernatants, %

Values are presented as mean ±SD. Superscript capital letters indicate the supernatants from which the corresponding value differed significantly in predefined pairwise comparisons (Welch's tests with Holm adjustment, adjusted p<0.05). Comparisons were performed separately within each concentration. The predefined comparisons were A vs B, A vs C, B vs D, A vs E, B vs F, C vs G, and D vs G.

The use of neutralised supernatants provided additional information on the contribution of acidity to the observed effects. Previous studies have shown that biofilm-inhibitory activity may persist after neutralisation of LAB-derived cell-free supernatants, indicating, that acidity is not necessarily the sole determinant of this effect (Alhubail et al., 2024).

In the present study, although neutralised CFS (CFS-N) and NFS (NFS-N) did not inhibit the planktonic growth of *S. aureus*, NFS-N at a concentration of 50 % still reduced biofilm formation by 42.3±9.4 %, and this effect was significantly greater than that of the neutralised medium control. Similar levels of inhibition were observed at the lower tested concentrations and did not differ significantly from the control. Direct pairwise comparisons between CFS-N and NFS-N did not reveal statistically significant differences at any tested concentration, indicating that the present data do not demonstrate superior antibiofilm effect of NFS-N over CFS-N. Nevertheless, the retention of biofilm-inhibitory activity after neutralisation suggests that factors other than acidity alone may have contributed to the observed effect.

Because NFS was obtained by centrifugation without subsequent membrane filtration, it may have retained cellular or subcellular material that differed quantitatively or qualitatively from the filtered CFS. However, the presence and contribution of such components were not directly determined in the present study. Comparative studies using cell-free supernatants, inactivated cells and combined preparations further indicate that soluble metabolites and cell-associated components may contribute differently to antimicrobial and biofilm-inhibitory activity (Falqueto et al., 2026). *L. helveticus* has been shown to release membrane vesicles and other high-molecular-weight material into culture supernatants, demonstrating that particulate extracellular components can occur in this species (Bringer et al., 2026).

Overall, both *L. helveticus* preparations exhibited strong concentration-dependent antibacterial and biofilm-inhibitory activity against *P. aeruginosa* and *S. aureus*. At concentrations at or above the MBC, inhibition of biofilm formation largely coincided with near-complete suppression of planktonic growth and therefore most likely reflected, at least in part, the strong antibacterial effect. At the lowest concentration of 6.25 %, substantial inhibition of biofilm formation persisted despite a weaker and more variable effect on

planktonic growth. At this concentration, differences between CFS and NFS became more apparent, particularly against *P. aeruginosa*, whereas such differences were less evident under bactericidal conditions.

Following neutralisation, planktonic growth inhibition was lost, whereas NFS retained a more pronounced biofilm-inhibitory effect against *S. aureus* than CFS-N. These findings suggest that, although acidity and soluble metabolites are major contributors to the activity of both preparations, additional pH-independent factors may contribute to the biofilm-inhibitory effect of the heat-treated, non-filtered supernatant.

The inability to distinguish the individual contributions of heat treatment and membrane filtration to the observed effects represents a limitation of this study, as no separate controls were included to assess the effects of each procedure independently.

Conclusions

1. Both *Lactobacillus helveticus* cell-free supernatant (CFS) and heat-inactivated non-filtered supernatant (NFS) exhibited strong, concentration-dependent antibacterial activity and inhibition of biofilm formation against *Pseudomonas aeruginosa* and *Staphylococcus aureus*.
2. At concentrations of 12.5 % and above, both preparations nearly completely inhibited planktonic bacterial growth and biofilm formation.
3. At 6.25 %, planktonic growth inhibition decreased markedly, whereas biofilm formation remained substantially inhibited.
4. At 6.25 %, CFS retained substantially greater antibacterial activity against planktonic *P. aeruginosa* than NFS, whereas both showed comparable activity against *S. aureus*, indicating that the difference depended on the target microorganism.
5. In the *S. aureus* assays, neutralisation eliminated planktonic growth inhibition, whereas substantial antibiofilm activity was retained across all tested NFS-N concentrations (41.3-48.3 % inhibition). The effect was statistically significant at 50 %, 25 %, and 6.25 % NFS-N, but not at 12.5 %. Direct pairwise comparisons did not demonstrate significant differences between NFS-N and CFS-N.

Abstract
Cranberries, sour cherries and chokeberries are an important source of bioactive compounds and are widely used in the food industry for the production of preserves, jams, juices and other products. These berries are rich in polyphenols, anthocyanins, flavonoids, organic acids and vitamins, which contribute to their antioxidant properties. During berry processing, press residues are produced. The berry press residues contain valuable bioactive compounds and could be used for anthocyanin extraction. The aim of this research was to evaluate the total anthocyanin and phenolic content in the press residues of cranberry, sour cherry and chokeberry in order to determine their potential as raw materials for bio-based indicator production, as well as to assess the effect of freeze-drying duration on the stability of anthocyanin compounds. The results showed that the highest total phenolic (2.06 g GAE 100 g^{-1} dry matter) and anthocyanin (2262.25 mg C3G 100 g^{-1} dry matter) contents were found in chokeberry press residues. The duration of freeze-drying significantly ($p<0.05$) affected the anthocyanin content in sour cherry and chokeberry press residues. The obtained results indicated that berry press residues, especially chokeberry press residues, are a valuable source of bioactive compounds. Overall, the research highlights the potential of berry processing by-products as a sustainable and promising raw material for anthocyanin extraction, as well as their potential application as bio-based indicators in smart packaging systems.
Keywords: chokeberries, sour cherries, cranberries, by-products, bioactive compounds.

Introduction

The food industry, during the food production process, annually produces many by-products, for example, fruit and berry press residues that arise during the production of juices and other products. The press residues can constitute 10–60% of the initial mass of the raw material (Kruszewski & Boselli, 2024). The fruit and berry press residues are often considered as waste; however, they contain valuable bioactive compounds such as polyphenols, anthocyanins, dietary fibre, and other components. Therefore, in recent years, attention to the utilisation of such by-products has increased. The by-products could be used as a source of bioactive compounds in food and pharmaceuticals, and packaging materials (Zhang et al., 2025a).

Berries such as sour cherries, chokeberries, and cranberries are an important source of polyphenols and anthocyanins. Due to the high concentration of polyphenols and anthocyanins in chokeberries (Chamberlin et al., 2024), they have been considered some of the richest berry sources of polyphenols. However, bioactive compounds could also remain in berry press residues after juice extraction. That makes berry press residues a promising and sustainable source of bioactive compounds. As berry press residues contain pigments (anthocyanins), they could be used in the food industry as natural colourants or as functional components (Dias et al., 2020) in various innovative products, including smart packaging, where they could serve as bio-based indicators (Bao et al., 2026).

Cranberries (*Vaccinium macrocarpon* L.) are an important source of bioactive compounds, as they contain polyphenols, carotenoids, vitamins, organic acids, and dietary fibre (Varnaitė et al., 2022). Cranberries are commonly used in the production of jams and juices, which results in by-products such as press residues that are rich in polyphenols, anthocyanins, phenolic acids, and flavanol's (Franco-Londoño et al., 2025; Song et al., 2025).

Similarly, sour cherries (*Prunus cerasus* L.) are rich in antioxidants and polyphenolic compounds (Jawad et al., 2025). The main phenolic compounds found in sour cherries are catechin, epicatechin, quercetin glycosides, and kaempferol derivatives (Oksuz et al., 2019). Sour cherry press residues consist of fruit skins, pits, and pulp, which make up approximately 15–28% of the initial fruit mass (Teslić et al., 2023). Therefore, sour cherry press residues are considered a promising raw material for the development of new food products and a source of bioactive compounds.

Chokeberries (*Aronia melanocarpa*), also known as black chokeberries, are rich in anthocyanins, polyphenols, and flavonoids. Due to chokeberry's bitter and astringent taste, fresh berries are mainly used for juice production, as well as for the preparation of jams and purées (Kim et al., 2024). During juice production, press residues are produced as by-products, which contain anthocyanins and polyphenols in high concentrations. Therefore, chokeberry press residues can be used as a source of natural pigments (reddish-purple colourants) or as bio-based indicators in smart packaging applications (Kim et al., 2024).

Chokeberry press residues mainly consist of the insoluble fraction, including the remaining berry pulp, skins, and seeds (Roda-Serrat et al., 2022).

Anthocyanins are water-soluble flavonoid pigments responsible for red, purple and blue colours (Khoo et al., 2017). These compounds occur in plants, berries and fruits as a glycoside. Cyanidin-3-glucoside is one of the common anthocyanins present in berries and their press residues (Khoo et al., 2017). Anthocyanins also have the ability to change colour depending on the pH of the medium, which makes anthocyanins potential natural indicators in smart food packaging (Bao et al., 2026).

This kind of packaging can indicate a possible food spoilage by responding to pH changes in the product. However, the stability of anthocyanins must also be

ensured, as it is dependent on several factors such as temperature, light, pH, co-pigmentation, oxygen, sulphites, ascorbic acid and enzyme presence and activity (Enaru et al., 2021).

According to Roda-Serrat et al. (2022), the main anthocyanins in chokeberries (*Aronia melanocarpa*) are cyanidin glycoside derivatives: cyanidin-3-O-galactoside, but cyanidin-3-O-xyloside, cyanidin-3-O-gucoside and cyanidin-3-O-arabinoside are present in lower concentrations (Roda-Serrat et al., 2022). Sour cherries also contain various anthocyanin derivatives, such as cyanidin-3-glucoside, cyanidin-3-rutinoside and cyanidin-3-sophoroside (Teleszko & Wojdyło, 2015). In sour cherries, the anthocyanin content ranges from 90 to 1000 mg per 100 g of fruit mass (Wojdyło et al., 2019).

The content of bioactive compounds in berry press residues depends not only on the type of berries but also on the applied processing methods. Freeze-drying is one of the most widely used methods to preserve bioactive compounds (Nawawi et al., 2023). This method effectively reduces the moisture content of the material while preserving thermally sensitive compounds such as anthocyanins and phenolic compounds. Moreover, the freeze-drying process results in a more porous material structure, which might facilitate solvent access to cellular components and consequently improve the extraction efficiency of bioactive compounds (Babaei Rad et al., 2025).

However, the parameters of the freeze-drying process, such as drying time and temperature, might affect the stability and concentration of bioactive compounds. Furthermore, the anthocyanin content in berry press residues might differ between fresh and freeze-dried samples, as removing water from the material can increase the concentration of these compounds on a dry matter basis, while under certain conditions it can also affect their stability (Zhang et al., 2025b). At the same time, it should be taken into account that freeze-drying is an energy and time-consuming process; therefore, its practical applicability should also be evaluated from an economic and technological perspective.

Therefore, it is important to evaluate how freeze-drying conditions, especially drying duration, affect the anthocyanin content in berry press residues in order to assess the potential of these materials for anthocyanin extraction and their further use as bio-based indicators.

The aim of this research was to evaluate the total anthocyanin and phenolic content in the press residues of cranberry, sour cherry and chokeberry in order to determine the potential as raw materials for bio-based indicator production, as well as to assess the effect of freeze-drying duration on the stability of anthocyanin compounds.

Materials and Methods

Cranberry (*Vaccinium macrocarpon cv Stevens)*, chokeberry (*Aronia melanocarpa*), and sour cherry (*Prunus cerasus cv Łutówka)* press residues (Figure 1) were supplied by the company Ltd. ANEVA J. Cranberries were sourced from Latvia, chokeberries and sour cherries – from Poland. The berry press residues were obtained using a hydraulic pack press during juice extraction. After juice pressing, the berry press residues were packed into low-density polyethylene resealable zip-lock bags and frozen.

Cranberry and chokeberry press residues were obtained in November 2025, and sour cherry press residues in December 2025.

The berry press residues were stored in a freezer at -18 ± 2 °C until further analysis. Before the analysis, the frozen berry press residues were thawed at room temperature (18 ± 2 °C) for 12 h.

Figure 1

Berry press residues used in the research (cranberries, sour cherries, and chokeberries)

Freeze-drying of the berry press residues

The thawed berry press residue samples were freeze-dried using a freeze-dryer ALPHA 1-2 LD plus (Martin Christ Gefriertrocknungsanlagen GmbH, Germany). Two freeze-drying settings were applied to evaluate the effect of drying duration on the total polyphenols and anthocyanins content in the obtained freeze-dried berry press residues:

a) the pressure was 0.052 mbar, and the temperature of the ice condenser was set to –54±0.5 °C, the duration of the drying was 7 h 30 min;
b) then pressure was 0.044 mbar, and the temperature of the ice condenser was set to –54±0.5 °C, duration of the drying was 8 h 30 min.

Sample preparation

The 15 g fresh press residues were homogenised in a mortar. The freeze-dried berry press residue samples were ground into powder using a coffee grinder (Stollar, China).

pH

The pH of each fresh berry press residue sample was determined using a pH meter inoLab pH 7110 (WTW, Germany). The analyses were performed in accordance with the ISO 1842:1991 standard *'Fruit and vegetable products — Determination of pH'*, and measurements for each sample were carried out in triplicate.

Moisture content

A Moisture analyser AND MX-50 (A&D Company Ltd., Japan) was used to determine moisture content in the samples. The samples were dried to constant weight using glass fibre filters AND AX-MX-32-2 (diameter 78 mm). Fresh chokeberry and sour cherry press residues were dried at 105 °C cranberry and freeze-dried samples were dried at 85 °C, the drying temperature was reduced to obtain more accurate moisture determination while minimising thermal decomposition of sample components.

The analysis for the samples was repeated three times.

The data was recorded using the software 'WinCT-Moisture'.

Total phenolic content (TPC)

Sample preparation: 40 mL of an ethanol–water solvent (80:20, v/v) was added to 1 g of the berry press residue sample. Phenolic compounds were extracted from the obtained mixture by applying an ultrasound-assisted extraction. The extraction was carried out using an ultrasonic bath Sonorex Digitec DT 100 H (Bandelin electronic GmbH & Co. KG, Germany) for 15 minutes at 30 ± 2 °C. After extraction, the obtained solution was filtered through filter paper (pore diameter 0.45 μm), and the filtrate was diluted to a volume of 50 mL with an ethanol–water mixture (80:20, v/v) (Avena et al., 2025).

Modified Folin–Ciocalteu method based on the methodology described by Vernon L. Singleton and Joseph A. Rossi (1965) was used to determine total phenolic content (TPC) (Paganotti & Barbeira, 2024). 0.5 mL of the berry press residue extract was mixed with 2.5 mL of 10% Folin–Ciocalteu reagent. After 5 minutes, 2 mL of 7.5% Na_2CO_3 solution was added to the mixture. The mixture was incubated in the dark for 2 hours (Paganotti & Barbeira, 2024). After the incubation, the absorbance of the analysed sample was measured at a wavelength of λ = 765 nm using a UV-1900i UV-VIS spectrophotometer (Shimadzu Corporation, Japan). The total phenolic content was expressed as grams of gallic acid equivalents per 100 gram dry matter of sample (g GAE 100 g^{-1}) (Ozola & Kampuse, 2017; Zannou & Koca, 2022).

The total phenolic content analysis for the samples was repeated three times.

Total anthocyanin content (TAC)

Total anthocyanin content (TAC) was determined using a pH differential spectrophotometric method described by Jungmin Lee (Lee et al., 2005). Absorbance measurements were performed at wavelengths λ = 520 nm and λ = 700 nm using a UV-VIS Shimadzu UV-1900i spectrophotometer (Shimadzu Corporation, Japan).

Extract preparation: 30 mL of extraction solvent (85% ethanol and 15% 1.5 mol L^{-1} HCl) (v/v) was added to 1 g of the berry press residue sample. The obtained mixture was stirred for 30 minutes, after which the extract was filtered, and the press residues were additionally rinsed with 10 mL of the extraction solvent. The filtrate was diluted to a volume of 50 mL with the same solvent (Avena et al., 2025).

Total anthocyanin content was expressed as cyanidin-3-O-glucoside equivalents (C3GE) in mg per 100 g dry matter (mg C3GE 100 g^{-1}) (Lee et al., 2005). The analysis for each sample was performed in triplicate.

Statistical analysis

The obtained results were expressed as mean values±standard deviation (SD). One-way analysis of variance (ANOVA) was used to evaluate the statistical significance of the data, assuming a significance level of $p<0.05$. Tukey's post-hoc test (Tukey HSD) was used to determine significant differences among the samples.

Data processing and statistical analysis were performed using Microsoft Excel 2026 (Microsoft Corporation, USA) and GraphPad Prism 10.4.2 (GraphPad Software LLC, USA).

Results and Discussion

pH and moisture content

pH and moisture content are important properties that characterise the chemical stability and microbiological safety, and preservation of bioactive compounds of berry press residues. At low pH, the stability of phenolic compounds can be promoted, but high moisture content can induce some microbiological and enzymatic processes that can lead to the spoilage of valuable bioactive molecules.

In this research, it was determined that the pH values of the berry press residues differed significantly ($p< 0.05$). The lowest pH value was determined in chokeberry press residues (pH=2.52±0.04), whereas the pH values of sour cherry and cranberry press residues were higher, and there was no significant ($p>0.05$) difference determined (Table 1). Chokeberries are rich in organic acids and phenolic compounds, which contribute to the pronounced acidity of the berries and their relatively low pH values (Kulling & Rawel, 2008). In the research by Kusur et al. (2025), who also investigated chokeberry press residues, the pH was reported as 3.65. The difference in results could be related to several factors, such as berry cultivar, geographical and climatic conditions, and the methods used to obtain chokeberry press residues.

The moisture content of berry press residues after juice extraction ranged from 44.14 to 65.45%. Similar results were reported by Blicharz-Kania et al. (2025). In the present research, the highest moisture content was observed in sour cherry press residues, and the lowest was found in chokeberry press residues (Table 1).

Roda-Serrat et al. (2022) reported a moisture content of 65±1% for fresh chokeberry press residues. The moisture content of chokeberry press residues analysed in the present study was lower than the values reported by Roda-Serrat et al. (2022). The moisture content of berry press residues can be affected by many factors, such as berry cultivar, processing technology, and pressing efficiency.

The highest moisture content in this research was determined in sour cherry press residues (65.45±1.81%). The high moisture content in sour cherry press residues is related to the structure of the fruit pulp and the high-water content of the berries. In addition, a higher water-holding capacity of the cell walls and a greater proportion of juice-containing parenchyma tissues may contribute to higher moisture retention in sour cherry press residues after pressing (Schumann et al., 2020).

Ebrahimi et al. (2025) reported that the moisture content of fresh sour cherry press residues was 85.80±0.50% (Ebrahimi et al., 2025).

In the present research, the moisture content of berry press residues were decreased by freeze-drying. The freeze-drying was carried out at two different drying durations. It was found that after 7 h 30 min of freeze-drying, the moisture content decreased from 5.38 to 25.14%. The samples, which were freeze-dried for 8 h

30 min, had the lowest moisture content. The moisture content in the samples, which were freeze-dried for more than 8 h, ranged from 3.80 to 15.1%. The low moisture content in freeze-dried berry press residues improves the stability and makes them more suitable for pigment extraction.

The differences in moisture reduction kinetics between tested berry press residues are related to differences in the microstructure, chemical composition, and water-binding mechanisms within the berry matrix. During the initial stage of freeze-drying, free water is predominantly removed, whereas in further stages of the freeze-drying process bound water is removed from cell structures and polysaccharide matrices (Figura & Teixeira, 2023; Nowak & Jakubczyk, 2020). As sour cherry press residues have a more porous structure (Schumann et al., 2020) and have higher initial moisture content (65.45±1.81%), a rapid initial decrease in moisture content after 7 h 30 min of the freeze-drying process was conducted. The moisture content was reduced by approximately 92% compared to the initial moisture content. Continuing the drying process, the removal of bound water was slower. In contrast, cranberry press residues contain higher levels of pectins, dietary fibre, and other hydrophilic compounds. These compounds have a stronger ability to bind water, resulting in a more gradual and even reduction in moisture content throughout the freeze-drying process (Nowak & Jakubczyk, 2020).

For chokeberry press residues, the initial moisture reduction was lower than observed for sour cherry press residues; however, a rapid decrease in moisture content continued even after 7 h 30 min of freeze-drying. This observation indicates the differences in water-binding mechanisms and internal moisture diffusion within the berry matrix.

Similar observations of various berry matrices during drying processes have also been reported in studies investigating the stability of biologically active compounds during drying (Gricenko et al., 2026).

Table 1

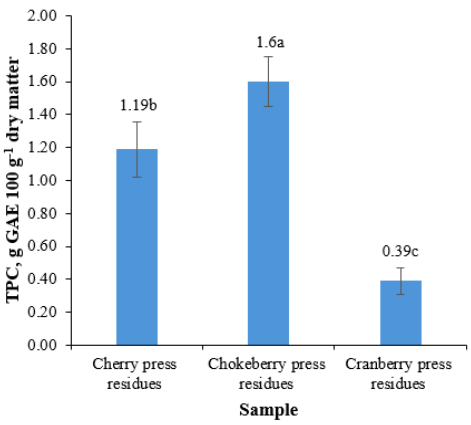
pH and moisture content of berry press residue samples before and after freeze-drying

Sample	pH	Initial moisture, %	7.5 h FD, %	8.5 h FD, %
Sour cherry press residues	3.61±0.06^{a}	65.45±1.81^{a}	5.38±0.13^{c}	3.80±0.78^{b}
Cranberry press residues	2.52±0.04^{b}	58.86±3.45^{ab}	25.14±1.31^{a}	15.1±1.09^{a}
Chokeberry press residues	3.57±0.01^{a}	44.14±1.09^{b}	11.99±0.40^{b}	4.59±0.22^{b}

FD-freeze-drying; initial moisture - moisture content after berry pressing.

Values are expressed as mean±standard deviation (n = 3). Different letters within the same column indicate statistically significant differences ($p < 0.05$).

Total phenolic compound content (TPC)



Berries that were used to obtain berry press residues are rich in bioactive compounds. The highest TPC was observed in fresh chokeberry press residues 1.6±0.16 g GAE 100 g^{-1} dry matter, whereas the lowest was found in fresh cranberry press residues 0.39±0.08 g GAE 100 g^{-1} dry matter (Figure 2). These differences in total phenolic content could be explained by the chemical composition of each berry and the distribution of different bioactive compounds within berry tissues.

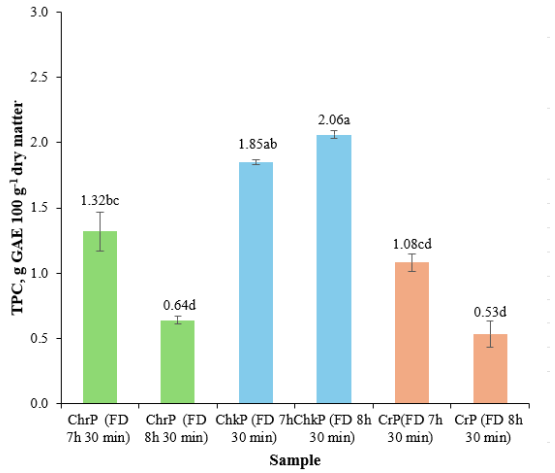
High TPC in chokeberry press residues was reported by Pădureţ et al. (2024). In their investigation, they found that TPC in chokeberry press residues reached 0.004 g GAE 100 g^{-1} (Pădureţ et al., 2024). In another research conducted by Denev et al. (2012), researchers determined that the total phenolic content of chokeberry berries ranged from 0.00069 to 0.0026 g GAE 100 g^{-1} (Denev et al., 2012). Similar results have also been reported in other studies – Tolic et al. (2015) found that TPC in chokeberry press residues reached 0.0042 g GAE 100 g^{-1} (Pădureţ et al., 2024; Tolic et al., 2015). The determined high TPC in chokeberry press residues can be explained by the fact that chokeberries are considered one of the richest sources of polyphenols among berries (Šimat et al., 2024). The dominant polyphenolic compounds in chokeberries are anthocyanins, proanthocyanidins, phenolic acids and flavonoids.

It is worth noting that the distribution of polyphenols within berries is not uniform; approximately 10% of polyphenols are found in the fruit pulp, 28–35% in the skins, and 60–70% in the seeds (Klavins et al., 2022). It should also be noted that the TPC in chokeberry press residues may vary significantly due to several factors, such as berry cultivar, growing and storage conditions, and pressing technology. Consequently, these factors may substantially affect the extraction and stability of bioactive compounds.

Figure 2

Total phenolic content (TPC) in sour cherry, chokeberry and cranberry press residues

Results are expressed as mean value ± standard deviation (n=3). Different letters indicate statistically significant differences ($p<0.05$).



The differences in TPC in the tested berry press residues are related to each berry's phenolic compounds profile. In cranberries, predominant compounds are proanthocyanidins, phenolic acids and flavonoids, which are related to the biological activity and antioxidant properties of the berries (Xu et al., 2025). The low polyphenol content in sour cherry press residues is related to the juice pressing process. During the process, a large portion of polyphenols is extracted in the juice (Repajić et al., 2025).

The total phenolic content (TPC) was also determined in freeze-dried berry press residues (Figure 3). The freeze-drying was carried out using two duration times: a) 7 h 30 min and b) 8 h 30 min. The obtained data showed that the drying duration affects the total phenolic content. After 7 h 30 min of drying, the TPC decreased by 52% in sour cherry press residues and 51% in cranberry press residues. In contrast, chokeberry press residues showed an 11% increase.

The increase in total phenolic content could be related to the stability of phenolic compounds that are present in chokeberries. The berries' skins and seeds contain a lot of phenolic compounds that remain in the press residues after juice processing.

Figure 3

Total phenolic content (TPC) in sour cherry, chokeberry and cranberry press residues after freeze-drying

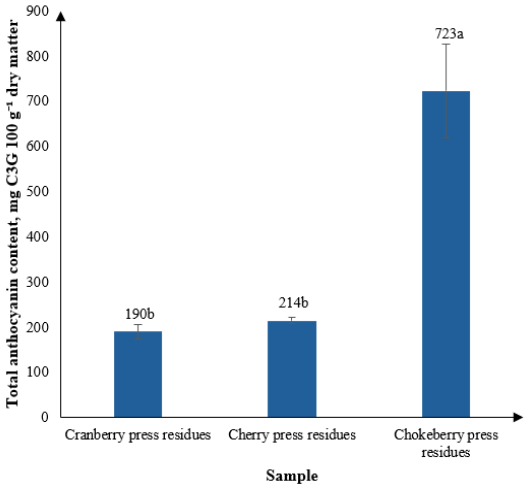
ChrP – sour cherry press residues; FD-after freeze-drying; ChkP - chokeberry press residues; CrP - Cranberry press residues.

Results are expressed as mean value ± standard deviation (n=3). Different letters indicate statistically significant differences ($p<0.05$).

The decrease in TPC in sour cherry and cranberry press residues after freeze-drying could be related to the lower stability of the phenolic compounds present. For example, sour cherries contain higher levels of anthocyanins. Anthocyanins are more sensitive to light and temperature changes and can be easily oxidized during sample preparation and juice processing. Consequently, a longer freeze-drying duration might promote structural changes and/or oxidation of polyphenols, thereby reducing total phenolic content. It would be necessary to analyse the individual phenolic compound profile of each berry press residue. The analysis could give a better insight into the stability of individual phenolic compounds.

Total anthocyanin content (TAC)

Total anthocyanin content in the samples was determined spectrophotometrically. The highest TAC was determined in fresh chokeberry press residues 723±104 mg C3G 100 g^{-1} dry matter. TAC in sour cherry and cranberry press residues ranged from 190 to 214 mg C3G 100 g^{-1} dry matter (Figure 4).



Roda-Serrat et al. had also studied TAC in chokeberry press residues and reported that the content of these compounds ranged from 284 to 686 mg 100 g^{-1} dry matter (Roda-Serrat et al., 2022). In our research, TAC converting to dry matter was 723±104 mg 100 g^{-1} dry matter. Total anthocyanin content can vary with many factors, such as chokeberry cultivar, growing conditions, degree of fruit ripeness, and the pressing method that was used for sample preparation.

The total anthocyanin content is also affected by each berry's tissue structure. Sour cherries and cranberries have a specific distribution of anthocyanins within berry tissues compared to chokeberries. When sour cherries and cranberries are pressed, a high concentration of anthocyanins is transferred into the juice fraction. That explains the lower anthocyanin content in the press residues of sour cherry and cranberry.

Anthocyanins are relatively unstable compounds that can degrade under the influence of oxygen, temperature and light, as well as during storage. During pressing, anthocyanins may undergo oxidation or degradation, reducing the total anthocyanin content in the berry press residues.

Figure 4

Total anthocyanin content (TAC) in fresh sour cherry, chokeberry and cranberry press residues

Results are expressed as mean value±standard deviation (n=3). Different letters indicate statistically significant differences ($p<0.05$).

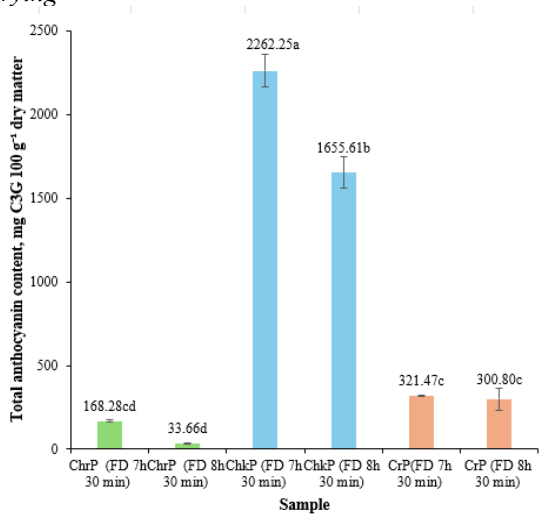


Figure 5 shows the total anthocyanin content (TAC) in freeze-dried berry press residues after 7 h 30 min and 8 h 30 min of drying. As shown in the figure, freeze-drying duration affects total anthocyanin content.

Prolonging the drying process by an hour led to a decrease in anthocyanin content. The TAC in sour cherry press residues decreased by 80%, in chokeberry press residues by 27%, and in cranberry press residues by 7%.

The results of the research indicate that freeze-drying duration can significantly ($p<0.05$) affect the anthocyanin content in berry press residues. An extended freeze-drying duration resulted in a significant ($p<0.05$) decrease in TAC in sour cherry and chokeberry press residues. However, the effect of an additional hour of drying of cranberry press residues was not statistically significant ($p>0.05$). This suggests that anthocyanin stability varies across berry species, and that freeze-drying could promote structural changes or oxidation.

Figure 5

Total anthocyanin content (TAC) in sour cherry, chokeberry and cranberry press residues after freeze-drying

ChrP – sour cherry press residues; FD-after freeze-drying; ChkP - chokeberry press residues; CrP - Cranberry press residues.

Results are expressed as mean value±standard deviation (n=3). Different letters indicate statistically significant differences ($p<0.05$).

At the same time, sample preparation and handling before freeze-drying should also be taken into account. For example, it is important to consider whether press residues are freeze-dried immediately after removal from the freezer or allowed to stand for a period before freeze-drying, as this could also affect anthocyanin stability.

Ross et al. reported that the retention of bioactive compounds in berry press residues is affected by the parameters and duration of the drying process, which could promote the degradation of polyphenols and anthocyanins (Ross et al., 2020).

This tendency partly corresponds with the results obtained in the present research. Furthermore, in the research by Ross et al., the TAC in the analysed cranberry press residues reached 147.22 mg C3G 100 g^{-1} dry matter, which is lower than the TAC determined in cranberry press residues in the present research 300.80 mg C3G 100 g^{-1} dry matter. These differences could be related to the cranberry cultivar and the freeze-drying parameters used.

Conclusions

1. The highest total phenolic and anthocyanin contents were found in fresh and lyophilised chokeberry press residues, indicating that these residues represent a valuable source of bioactive compounds.
2. The duration and parameters of freeze-drying affected the total anthocyanin content in berry press residues, particularly in sour cherry and chokeberry press residue samples.
3. Chokeberry press residues are a potential raw material for anthocyanin extraction and their further application in the development of bio-based indicators for food packaging.
4. The freeze-drying process of berry press residues should be more accurately studied to optimise the drying process. It is necessary to determine the optimal freeze-drying duration to maintain anthocyanin stability.

HIGH-POWER CHARGING SOLUTIONS FOR ELECTRIC TRANSPORT: REVIEW OF EXISTING TECHNOLOGIES AND APPROACHES

***Mārtiņš Tisenkopfs, Aigars Laizāns**
Latvia University of Life Sciences and Technologies
*Corresponding author's email: martins.tisenkopfs@gmail.com

Abstract
High-power charging (HPC) systems are becoming a critical enabling technology for the rapid electrification of heavy-duty, industrial, and mission-critical transport sectors. This review analyses converter topologies, energy-storage-integrated architectures, and microgrid configurations that define the performance, scalability, and stability of next-generation HPC infrastructure standardization (MCS, CCS), IT communication protocols (ISO 15118, OCPP) and microgrid configurations that define the performance, scalability, and stability of next-generation HPC infrastructure. The study shows that advanced AC/DC and DC/DC topologies – such as Vienna rectifiers, three-level NPC converters and modular multilevel converters-support the transition toward Megawatt-level charging systems while maintaining high efficiency and reduced harmonic distortion. Energy storage integration, especially an energy storage system connected to a DC bus, reduces the peak load of the grid by approximately 30-70% and can reduce voltage fluctuations by 4-8%, allowing systems to be integrated in locations where grid reinforcement is limited. Hybrid AC/DC microgrids can increase the flexibility of the power grid, reduce conversion losses by approximately 10-15%, and improve resilience in networks with pronounced demand peaks, such as those in airports, ports, and agricultural infrastructure. Predictive and AI-based charging strategies can further improve grid efficiency by approximately 10-25%, as they optimize charging schedules and electricity distribution in specific situations. The findings highlight that HPC deployment is most successful when based on topological system-level design rather than isolated technological improvements. The paper provides a structured comparative analysis and proposes topology-aware pathways to support scalable, stable, and sector-specific HPC deployment in climate-neutral transport systems.
Keywords: high-power charging, electric vehicles, microgrid, energy storage, smart control.

Introduction

The rapid electrification of transport systems is becoming one of the central pillars of the European Union's climate-neutrality strategy, as outlined in the European Green Deal and national frameworks such as Latvia's updated National Energy and Climate Plan (NECP) (National Energy and Climate Plan 2021-2030). While the electrification of light vehicles is progressing steadily, with charging infrastructure largely relying on the existing energy supply network, sectors such as agriculture, airport ground operations, public transport and port operations show significantly different operational profiles and energy requirements for transport units and notably for charging systems. These sectors are characterised by highly visible working conditions where downtime can significantly impact productivity, making it particularly important to provide them with reliable, high-power (HPC) infrastructure capable of providing 300-2000kW of charging capacity in short periods of time (Tietz et al., 2025; Kumar et al., 2019). This applies to the light and heavy vehicles used there, as well as the related technical equipment.

However, such high-intensity irregular charging events impose sudden and significant load peaks on distribution grids that were not originally designed to support transient megawatt-scale power flows. Observational studies show voltage instability, thermal overloads and reduced power quality when high-power charging stations are operated without solutions that reduce problems, risks or negative impacts (Kapoor et al., 2023; Maghami et al., 2025) Infrastructure upgrades, such as transformer replacement, additional deployment or grid capacity expansion, often involve a complex set of administrative procedures and high capital investments, so these solutions cannot be considered as the only and real solution for large-scale HPC deployment (Schoenberg et al., 2023).

Consequently, research and development is underway on integrated architectures that combine high-efficiency power electronics, local energy storage systems (ESS), renewable energy support and improved microgrid management. Studies show that combining energy storage with charging systems reduces the peak power demand of the grid by 30-70% depending on the configuration and operating models (Karimi et al., 2022; Agajie et al., 2023), while HPC systems connected to microgrids increase overall flexibility and resilience (Paule et al., 2025), in particular, research shows that in sectors such as aviation ground handling and port operations. For example, Zoutendijk & Mitici (2024) research demonstrates how airport ground operations create demand peaks that exceed the current infrastructure capacity, unless local buffering and predictive management solutions are used (Zautendijk & Mitici, 2024). Alfredsson et al. (2024), in their research, similarly conclude that implement fully electrified aviation ground operations services will require entirely new HPC topologies and grid-support structures (Alfedsson et al., 2024) A particularly important challenge that is still underexplored is the topology of HPC systems, combined with standardized communication and charging protocols to create complete infrastructure solutions. HPC implementation involves much more than just power electronics solutions, it is a complex and integrated approach, that includes a megawatt charging system (MCS) for heavy-duty vehicles and complex IT management systems that it combines a coordinated AC/DC conversion stage, DC/DC converters, ESS interfaces, bus voltages and microgrid layer

deployment (Hellgren et al., 2023). Power quality is largely determined by the power converter solution chosen, how efficient, stable, safe and usable the HPC charging system will be, including they determine harmonic spectrum, dynamic response, thermal performance and compatibility with future 800-1500 V electric vehicle platforms. Recent studies highlight that methods such as Vienna rectifiers, three-level neutral-point-clamped (NPC) converters, modular multilevel converters (MMC), dual-active-bridge (DAB) DC/DC converters, and resonant converters (LLC), which is a high-efficiency DC/DC converter topology, are increasingly being used for high-power charging, as they provide higher efficiency and lower total harmonic distortion (THD) (Safayatullah et al., 2023; Mateen et al., 2023; Arena et al., 2024; Atanalian et al., 2023).

Studies on the development of microgrids show that the choice between AC, DC and hybrid AC/DC topological solutions affects the system efficiency, energy storage capacity and also affects the integration of renewable energy resources, their fault tolerance in HPC nodes (Urooj & Nasir, 2024; Modu et al., 2023). The available literature sources are still fragmented and only a few studies review a unified comparative analysis of high-power charging topologies in different transport sectors and network usage conditions.

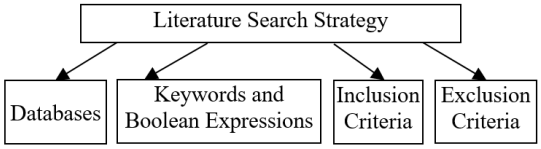
For this reason, the aim of this review is to review the analysis of high-power charging topologies in different transport sectors and network usage conditions, reviewing existing studies on high-power charging systems, paying special attention to topological architectures, their operation and sector-specific requirements.

The objectives of the article are:

1. To identify and classify the main problems associated with the implementation of high-power charging in agriculture, public transport, aviation and port operations;
2. Describe and compare different types of high-power charging converter topologies (AC/DC and DC/DC), topologies with energy storage system integration, and commonly used microgrid architectures;
3. Evaluate predictive control algorithms and control approaches that improve the performance of high-power charging (HPC) topologies under limited network capacity conditions;
4. Analyze the selection guidelines for existing topologies, taking into account the operating environment and power system constraints;
5. Provide a comprehensive overview and assessment of the development prospects of HPC infrastructure.

Based on previous research findings in power electronics, microgrid engineering, power system modeling, and industry experience, the article provides a technically sound and practically applicable perspective on existing high-power charging architectures, as well as insight into their development trends.

Materials and Methods



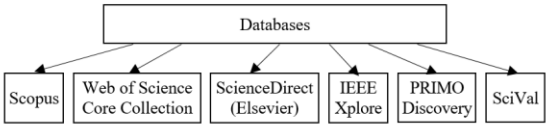
To create this review, a structured and systematic methodology was used to find, classify and evaluate existing research on high-power charging systems, and the associated operational constraints and technical topologies that have affected their implementation. The methodology was designed to ensure transparency, reproducibility and compliance with generally accepted scientific practice in literature reviews.

Literature Search Strategy

The literature search strategy is based on those stages, as shown in Figure 1.

Figure 1

Literature search strategy

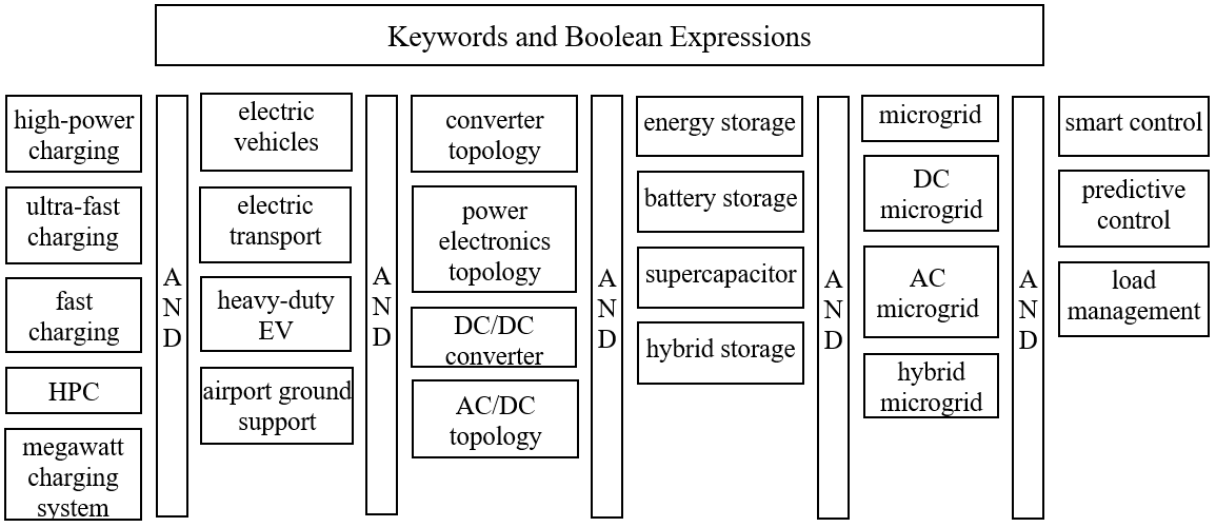


A comprehensive literature search was conducted in several internationally recognized scientific databases. In order to cover the most relevant studies in the field, databases with a high citation count were used, which help identify the most relevant studies, as well as those specializing in specific fields, such as power systems, transportation engineering, power electronics and microgrid design. The availability of full text was also an important factor, so that full articles could be analyzed before being included in the review.

The databases that were used are shown in Figure 2.

Figure 2

Used databases



This review covers publications from the last decade (2015 to 2025) in both Latvian and English. Reviewing literature in both languages provided a deeper understanding of the context and effectively captured rapid technological development in high-power fast-charging architectures, power converter topologies, and energy storage integration.

Keywords and Boolean expressions

In creating the index, search queries were focused on keywords, phrases, titles, summaries, keywords. The set of Boolean expressions included the questions that are shown in Figure 3.

The methods given in the scheme ensured the inclusion of studies that are directly related to high-power charging infrastructure, with a special emphasis on topology, as well as network integration and system-level design.

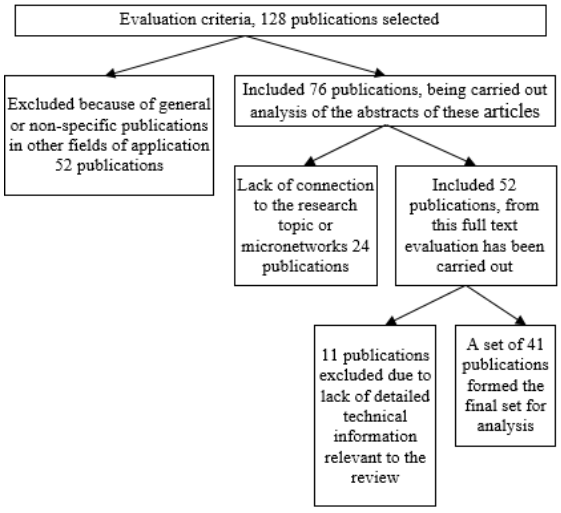


Figure 3
Keywords and Boolean expressions schema for literature search

Inclusion and Exclusion Criteria
These criteria determine which studies or data may be included in the study and which may not.
Inclusion Criteria
Publications were included in the review if they addressed high-power or ultra-fast charging (≥150 kW), network integration, power converters, energy storage systems, or microgrid architectures. These included AC/DC converter topology, DC/DC converter topology, bus configuration or microgrid structure analysis, modeling, or experimental evaluation. For inclusion in the review, methodological features were assessed, and publications that provided empirical data, modeling results, simulations, and prototype testing, as well as publications that discussed formal optimization methods, were included.
Exclusion Criteria
Publications were subject to multiple levels of exclusion criteria. Initially, as shown in the table, a check of titles and keywords was performed, and 52 publications were excluded that had a general or off-topic application. This was followed by an analysis of abstracts from the 76 publications that had passed the previous selection. At this stage, publication abstracts were analyzed, and publications were excluded if their abstracts were not related to the topic of the review study or microgrids. When performing this selection, 52 publications met the criteria, as shown in the table. At the final stage of publication selection, the full texts of the publications were evaluated, and exclusion was performed if the publications focused only on low-power charging, only considered the charging of light electric vehicles, were not scientific, lacked methodology, and did not provide engineering insights. After analyzing the literature, 41 publications were deemed eligible for inclusion in the review, the full process of which is mapped out in Figure 4.

Thematic Categorization of Publications
To ensure a transparent analysis of the research, all included studies were categorized into thematic groups, each of which covers a part of the topic under consideration. The following groups were distinguished: articles on network load and stability analysis, articles on high-performance charging demand modeling for heavy-duty electric vehicles, publications on energy storage integration and hybridization, as well as power grid topologies, microgrid architectures, and control algorithms; and specific articles related to agricultural, airport, port, and public transport research relevant to the topic of the article.

Figure 4
Evaluation criteria

This classification supports a structured comparison across different technological dimensions. These categories allowed for a comparative analysis of the

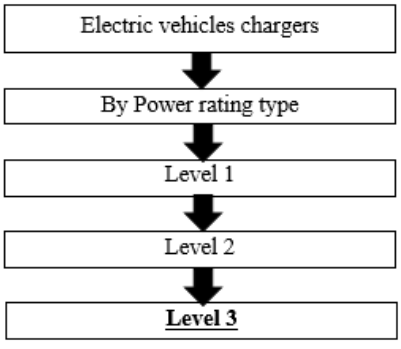
latest high-power charging infrastructures, which formed the basis for the 'Results' and 'Discussion' sections.

Methodological Limitations

Limitations of the review:

- The rapid pace of development of high-power charging stations and new topologies after 2025 is not yet widely documented, and information on the established charging infrastructures is not published.
- Lack of real-world case studies for 1-2 MW industrial high-power systems.
- Limited public data on the charging architectures used.

However, the methodological framework provides a comprehensive and replicable basis for a review of the topologies of existing high-power charging systems and their associated impact on the power system.



Results and Discussion

Overview of High-Power Charging System Topologies

Fast charging of electric vehicles can be performed with alternating current or direct current. The main difference in these charging methods is that in alternating current charging, the current is converted to direct current inside the electric vehicle; therefore, for fast charging, direct current is used, bypassing the converter built into the electric vehicle and its associated limitations (Ivarsøy, 2020). Modern electric vehicle charging infrastructures can be divided into several levels according to their capacity, as shown in Figure 5, dividing chargers according to their capacity. The solutions reviewed in the review are from level 3 and higher.

Figure 5

Types of electric charging according to their power ration type

Fast charging is defined with a capacity starting from 50 kW and a charging time of less than 30 minutes, while ultra-fast charging is defined with a capacity above 400 kW, which allows charging the vehicle's battery in less than 10 minutes (Zeb et al., 2025). With the development of heavy electric transport (electric tractors, trucks, ships, and aviation), the Megawatt charging system standard is being introduced, which aims to achieve up to 3.75 MW of power (1250 V/ 3000 A) (Alfedsson et al., 2024; Hellgren et al., 2024). Fast charging is a key prerequisite for reducing vehicle downtime and making electric vehicles more competitive in terms of performance with internal combustion engines (Zeb et al., 2025). Fast charging is essential for sectors such as agriculture, heavy transport, maritime shipping and aviation. Implementing fast charging during short operational breaks minimizes vehicle downtime, making it increasingly viable for these high-demand industries (Tietz et al., 2025; Ramberg & Levin, 2024).

Insights from the German truck infrastructure modeling by Tietz et al. (2025) suggest the need for high-power charging (HPC) in combination with night-time charging in logistics parks study concluded that this approach gives the best results (Tietz et al., 2025). Swedish action research on the feasibility of implementing charging infrastructure for heavy-duty electric vehicles operating in the construction sector shows that low-power night-time charging creates less grid load than high-power daytime charging, which takes place during the day, also because more HDEVs are charged at night (Ramberg & Levin, 2024). Most Norwegian research on the planning of fast charging stations (FCS) is focused on optimizing the location and layout of stations to reduce network losses and increase social benefits (Kapoor et al., 2023).

Main challenges in implementing high-power charging

In a study on truck charging and the creation of a fast charging network to decarbonize long-distance cargo transport, Tietz et al. (2025) focus on Germany while citing examples from Sweden. There, high-power mobile charging stations with buffer batteries have been studied to reduce the load on existing electricity grids. The authors emphasize the need for a minimum charging capacity of at least 720 kW, which poses a significant challenge for existing electricity networks (Tietz et al., 2025; Ramberg & Levin, 2024).

The next sector examined in the review is public transport, and the study by Prussi et al. (2024) examines solutions where trams in urban environments are equipped with fast-charging batteries or supercapacitors that are charged at stops, allowing trams to travel even in sections where there is no wired electrical network. The biggest challenges in this sector are peak load management and integration with existing infrastructure, such as the existing tram DC network described. Coordination of the movement schedule should also be mentioned as a challenge, as traffic is often unpredictable and optimization algorithms are complex (Zautendijk & Mitici, 2024).

In studies on ship and port infrastructures, a fast charging system is used that is supplied from the grid, but is also supported by shore-side batteries (OSB). Focusing on shore-to-ship power to provide zero-emission ferry traffic, the study examines shipping in the Baltic Sea and Norwegian fjords. The study compares three general S2SC solution power system architectures in terms of energy efficiency for AC, DC and inductive charging. Fast charging ports can charge

ships within 2 hours using charging connections on shore (Karimi et al., 2022; Kumar et al., 2019). It is concluded that problems can arise if there is a lower ratio of direct grid power to the total charging capacity, due to a lower energy efficiency of the system. This is due to energy losses that occur during the charging and discharging process of shore-side batteries. Problems also arise due to the lack of space on shore and the need for galvanic isolation for safety reasons (Kumar et al., 2019).

In aviation, business continuity and tight schedules – along with the short time aircraft spend on the ground between flights - make fast charging crucial. Consequently, studies in this sector examine megawatt charging systems capable of delivering up to 3000 A current and megawatt-level power (Alfedsson et al., 2024). The main challenges are related to the critical load that these charging stations place on airport networks, as well as the strict safety requirements such as fire hazard, electromagnetic interference (Alfedsson et al., 2024). Studies show that hybrid AC/DC microgrids in combination with DC coupler energy storage (ESS) at airports provide the most robust energy storage configuration, especially in the case of peak demand of 1 MW for a few minutes (Berdahl et al., 2020; Ahmad et al., 2025).

In the agricultural sector, studies describe challenges regarding charging infrastructure, noting that this sector predominantly uses private charging stations rather than public charging networks (Riedner et al., 2018). There is a strong interest in the use of renewable resources, mainly solar panels. Studies show that farms with their own energy storage infrastructure are more motivated to introduce electric vehicles on their farms. However, there is often a lack of grid capacity, high-power charging, especially in rural areas, so several studies are being conducted in this sector that could increase the number of mobile charging stations with energy storage systems that may not have an independent grid connection to ensure their operation, for example, in the field (Ramberg & Levin, 2024). Similar to other sectors, the main obstacle to introducing electric vehicles in agriculture is the long charging time. Furthermore, because heavy battery infrastructure can account for approximately 40% of a tractor's weight, it significantly increases the risk of soil compaction. Finally, research highlights logistical hurdles, such as the need for specialized rental agreements (Ramberg & Levin, 2024; Riedner et al., 2018; Lagnelöv et al., 2021).

Research conducted in Latvia is focused on ensuring the current stability of the grid and increasing energy efficiency in these sectors. For example, studies by Rubenis et al. (2025) focus on bidirectional energy transmission (V2G). This allows vehicles to become an active part of the grid, adjusting charging depending on the grid load and price, this approach reduces the peak load on the grid. Studies show that energy efficiency improves by 20-30% compared to unmanaged charging strategies. Researchers at Riga Technical University have studied an integrated multi-energy community hub for several houses, which can be installed with rooftop solar panel systems with a total capacity of 51 kW, such a solution increases self-consumption and creates greater grid flexibility (Paule et al., 2025). By the end of 2023, more than 20,000 small energy producers with a capacity of over 560 MW were connected to the grid in Latvia, the majority of which are solar energy systems, but there has been an increased interest in energy storage solutions, which are a crucial factor for fast charging capacity in regions where grid energy consumption is limited (Zemite et al., 2024).

Charging Standards and IT Infrastructure

To improve the applicability of the system, which covers electric vehicles from different manufacturers, charging stations, energy storage systems and power grids, it is imperative to introduce international standards. Research indicates that a standardized megawatt charging system (MCS) for heavy vehicles is being developed, designed to support charging power up to 3.75 MW (1250 V / 3000 A), which is very important for trucks and electric aviation (Hellgren et al., 2023). While the combined charging system (CCS) supports up to 400 kW, the MCS provides the necessary scalability for large batteries (Hellgren et al., 2023). The IT infrastructure and communication protocols are the 'brains' of HPC solutions. ISO 15118 (specifically ISO 15118-20) defines the communication between the vehicle and the charger, enabling 'Plug & Charge' and 'Vehicle-to-Grid' (V2G) capabilities. At the same time, the Open Charging Point Protocol (OCPP 2.0.1) facilitates communication between the charging station and the management system (CSMS), enabling real-time load balancing and smart charging management (Hellgren et al., 2023).

High-power charging converter topologies

In high-power charging stations AC/DC architectures:

- AC-DC rectifiers, often using a Wien rectifier to provide a high power factor, are widely used due to their high efficiency, low total harmonic distortion (THD), and unidirectional power density (Zeb et al., 2025; Bharaneedharan et al., 2024).
- NPC (Neutral Point Clamped) converters provide a bipolar DC bus and bidirectional power flow but are more expensive, and their control is more complex. Neutral point clamps (NPCs) are widely used in 350-600 kW chargers due to their high voltage capability and reduced semiconductor voltage (Zeb et al., 2025).
- T-shaped and active neutral point clamp (ANPC) converters, which support improved harmonic suppression and flexible modulation schemes (Sadeghi et al., 2022).
- Modular multilevel converters (MMCs), are becoming the preferred architecture, especially for megawatt charging systems with a capacity of 1-2 MW, due to their scalability, fault tolerance and excellent waveform quality (Barresi et al., 2022; Rodriguez et al., 2022).

In high-power charging stations DC/DC architectures:

- Non-isolated (interleaved buck) has a modular design and low current ripple but lacks galvanic isolation, which is a safety risk (Zeb et al., 2025).
- Isolated (Phase-Shifted Full-Bridge (PSFB) and LLC) are popular due to their high power density. LLC
- resonant converters provide ‘soft’ switching and low EMI. These resonant converters provide high efficiency in the 20-200 kW range, but their design is difficult due to the nonlinear charging profile (Zeb et al., 2025; Peng et al., 2025).
- The Dual Active Bridge (DAB) is recommended for bidirectional power flow from vehicle to grid (V2G) with built-in soft-switching capability, where transistors switch when the voltage is very low or the current is very low, and modular scalability that can gradually increase the system according to the required power, electric vehicles not only consume energy, but can also return it to the grid (Zeb et al., 2025; Chaudhury & Kastha, 2025).
- Research shows that interconnected buck and multi-port converters appear in modular charging solutions that provide flexible power sharing across multiple charging outputs (Elkeiy et al., 2023).

Studies consistently emphasize that DC microgrids offer the highest efficiency for multi-MW charging infrastructure, while hybrid architectures offer the best compromise between efficiency and compatibility with existing infrastructure (Azeem et al., 2021; Feng & Chi, 2021).

Microgrid architectures:

- AC microgrids are becoming less widely used because their use requires a higher number of conversion stages; for example, solar panels produce DC, which is converted to AC with the help of an inverter. If this energy needs to be stored, then the energy is stored in batteries, and this energy must be converted back to DC.
- DC microgrids are becoming a priority because they reduce the number of energy conversion stages, for example, from solar panels and batteries directly to electric vehicles, thus reducing losses (Berdahl et al., 2020).
- Microgrid Architectures and Efficiency AC and DC microgrids are core components of HPC hubs. While AC networks remain the standard for low-power applications, DC microgrids are becoming a priority for high-power installations (Berdahl et al., 2020). This shift is technically justified because DC distribution reduces the number of energy conversion stages; for instance, PV panels, batteries (BESS), and electric vehicle batteries all operate natively on DC (Berdahl et al., 2020). By eliminating redundant AC - DC and DC-AC conversions, DC microgrids can reduce energy losses by 10-15% and significantly improve overall system efficiency. This configuration also simplifies the control structure and allows for higher current capacity in localized energy hubs (Berdahl et al., 2020).

Predictive Control Algorithms and Approaches

Under capacity constraints, studies have shown that Model Predictive Control (MPC) and its corresponding network regulation power and thermal constraints can be improved by optimizing charging in real time. Smart charging algorithms, such as those based on the ISO 15118 standard for dynamically adjusted charging and load-dependent charging, provide dynamic charging capacity adjustment depending on the network load and the price of each exchange and peak demand, thus reducing electricity costs by 20-30% (Rubenis et al., 2025). Quadratic Programming (QP) is an optimization method where the objective function is quadratic, but the constraints are usually linear. In the case of airports, real-time QP algorithms allow prioritizing aircraft charging, largely attacking flight time and available power (Alfedsson et al., 2024). Heuristic algorithms (ALNS, PSO) and loss methods that search for a good (not always perfectly optimal) solution to complex problems, where classical network methods as well as investment optimization methods (e.g., QP) become too slow or unusable due to costs (Zautendijk & Mitici, 2024).

Future research focuses on the use of artificial intelligence (AI) in battery management systems to more accurately predict SoC (State of Charge) and SoH (State of Health), thereby extending battery life under aggressive, high-power charging cycles (Devi et al., 2026).

Guidelines for choosing topologies

Topologies of systems depend on the operating environment and constraints, e.g., AC-coupled BESS (T1 topology) are simpler and with higher technology readiness (TRL), but DC bus topologies (T2/T3) offer better scalability for the creation of future energy hubs (Alfredsson et al., 2024). If any spatial constraints are defined, such as urban environments and airports, then the choice of topologies should be given preference to ground installations, or mechanized solutions to save space, as integrated (Alfedsson et al., 2024). In terms of mobility, it is described in places where the use of stationary infrastructure is not economically advisable, such as fields and construction sites (buffer batteries) (Ramberg & Levin, 2024).

HPC infrastructure development prospects

The future of HPC infrastructure is moving towards integrated and decentralized energy management. How it should be developed is the transition to new materials, such as the use of silicon carbide (SiC) and gallium nitride (GaN) in converters, they reduce the size and heat loss by more than 70% (Zeb et al., 2025). Smart microgrids with individual charging stations will evolve into multi-energy community hubs that combine RES generation, BESS, and V2G service network stability, as already available studies show (Paule et al., 2025). The introduction of megawatt charging systems is essential; the introduction of such a standard electrical system will allow for MW-level charging capacities to be achieved, making electric vehicles competitive with internal combustion engine

vehicles (Ramberg & Levin, 2024). The use of AI and digital twins is increasingly important; specifically, the integrating artificial intelligence into battery management systems allows for more accurate SoC prediction, thereby extending the service life of battery packs (Rahman et al., 2025; Kurkin et al., 2025).

Table 1

Comparative Analysis of HPC-Related Topologies

Topology Type	Specific Topology	Power Range	Efficiency	Harmonics / PQ	Scalability	Dynamic Response	Strengths (Applications)	Limitations
AC/DC Converter Topologies	Vienna Rectifier	150-600 kW	96-98%	Low THD (2-5%)	Medium	Medium	High-efficiency front end for bus depots, logistics chargers; compact size	Unidirectional power flow; not ideal for V2G or hybrid ESS
	3-Level NPC Converter	150-800 kW	96-98%	Low THD (3-7%)	High	High	Stable high-power charging; compatible with 800-1000 V platforms	More complex control; increased component count
	Active NPC / T-Type Converter	150-750 kW	97-98%	Very low THD	Medium-High	High	Lower switching losses; good harmonic suppression for aviation GSE chargers	Thermal balancing challenges
	Modular Multilevel Converter (MMC)	500 kW-2 MW	97-99%	Excellent PQ	Very High	High	Best option for mega-watt charging (airports, ports); high voltage capability	Complex control; higher cost
DC/DC Converter Topologies	Dual Active Bridge (DAB)	50 kW-1 MW	96-98%	N/A	High	Very high (sub-ms)	Bidirectional charging, ESS integration; excellent for depots and airports	Requires precise control; EMI considerations
	LLC Resonant Converter	20-300 kW	95-97%	N/A	Medium	High	High-frequency operation, compact form; good for modular chargers	Limited scalability to MW-class
	Interleaved Buck / Multiport	20-800 kW	94-97%	N/A	High	Fast	Flexible output distribution; good for multi-user charging hubs	Lower efficiency at very high power
ESS Coupling Topologies	AC-Coupled Battery ESS	100 kW-5 MW	92-96% system	Supports grid THD reduction	Medium	Medium	Easiest retrofit; grid-side buffering for depots and ports	Two conversion stages → higher losses
	DC-Bus-Coupled ESS	100 kW-2 MW	95-98% system	Direct support to charger	High	Very High	Reduces peak loads by 30-70%; ideal for airports, agricultural hubs, high peaks	Requires aligned DC bus voltages
	Hybrid ESS (Battery + Supercapacitor)	50 kW-2 MW	95-98%	Excellent smoothing	High	Extremely high	Reduces transient stress 15-30%; stabilizes pulsed loads	Higher initial CAPEX
System-Level / Microgrid Topologies	AC Microgrid	100 kW-10 MW	Moderate	Grid-dependent	Medium	Medium	Compatibility with existing infrastructure; suitable for public transport	Higher conversion losses (5-8% more than DC MG)
	DC Microgrid	100 kW-10 MW	High (loss reduction 10-15%)	Very stable	High	High	Efficient multi-charger clusters; avoids multiple conversions; ports & bus depots	Requires harmonized converter interfaces
	Hybrid AC/DC Microgrid	100 kW-20 MW	High	High	Very High	High	Best flexibility; integrates renewables, ESS, HPC under constraints; optimal for airports	Higher control complexity; coordination layers needed

To better understand high-power charging topologies, they are summarized in Table 1. The summary demonstrates that no topology is universal and optimal for every situation, the choice depends on the requirements of the specific application.

Comparative Analysis of HPC-Related Topologies

A critical conclusion derived from current research is the necessity of ‘peak shaving’ to protect the utility grid from high-power demand spikes (Hellgren et al., 2023; Kapoor et al., 2023). Peak shaving is achieved by integrating Battery Energy Storage Systems (BESS) that act as an ‘energy buffer’ (Karimi et al., 2022).

Battery Energy Storage Systems (BESS) can be charged from the grid during periods of low demand, such as at night when electricity consumption is lower. These systems can return the stored electricity during high-power charging, effectively helping to reduce the peak power consumed from the public grid (Hellgren et al., 2023). Studies show that the peak grid load can be reduced by 30-70%, avoiding expensive grid reconstructions and the need for larger transformers. To improve the use of BESS, it is possible to use dynamic charging capacity limitation, where the charger adjusts its capacity based on real-time grid constraints, which further helps to reduce the grid load (Ramberg & Levin, 2024; Kapoor et al., 2023).

Conclusions

1. In high-power charging stations, the most efficient AC/DC conversion efficiency is provided by Vienna

rectifiers, which guarantee high efficiency and low total harmonic distortion (THD). In DC/DC transmission, priority is given to isolated topologies (such as PSFB and LLC resonant converters), which provide galvanic isolation, that is, there is no direct electrical connection between the two electrical circuits, and thus ensure user safety.

2. Successful implementation of high-performance high power charging (HPC) is not limited to the choice of power electronics, it is a complex and comprehensive approach, requiring full integration with international standards, such as the Megawatt Charging System (MCS). The MCS is designed to provide charging capacity up to 3.75 MW (1250 V / 3000 A) for the heavy transport and aviation sectors. Such standardization is crucial to ensure infrastructure interoperability and scalability across different transport sectors.

3. Smart control algorithms (MPC, QP) combined with standardized IT communication protocols that ensure data exchange and interoperability between charging system components, such as ISO 15118-20 and OCPP 2.0.1, serve as the 'brain' of the system. These algorithms enable real-time power distribution, Vehicle-to-Grid (V2G) functionality, and grid load balancing, which are essential for managing large-scale charging hubs.

4. The integration of stationary Battery Energy Storage Systems (BESS) is a technically and economically justified solution for 'peak shaving'. It can reduce peak loads on the electrical grid by 30-70%. This system and approach is an indispensable tool for avoiding expensive investments in grid expansion and the installation of high-capacity transformers in areas with limited grid capacity.

5. In high-power charging stations, direct current (DC) microgrids are touted as a more efficient solution compared to alternating current (AC) microgrids, as they significantly reduce the number of energy conversion stages. Since photovoltaic panels, battery-powered energy storage systems (BESS), and electric vehicle batteries are inherently DC voltage environments, a local DC architecture can reduce the overall system energy losses by 10-15%, thereby improving the cost-effectiveness of the infrastructure.

6. This review, based on a broad analysis of international literature (including HPC network modeling in Germany, fast-charging station planning in Norway, and simulations from the Swedish construction industry), provides a comprehensive insight into integrated HPC infrastructure solutions, identifying that the success of HPC implementation depends on topological system-level design rather than isolated technological improvements.

7. In the future high-power charging infrastructures will transition toward integrated 'Smart Energy Hubs' that harmonize local renewable generation, energy storage, and V2X capabilities. This evolution is driven by three key trends: the adoption of SiC/GaN semiconductors to maximize efficiency and power density, the application of AI and Digital Twins for predictive battery health and grid management, and the global standardization of Megawatt Charging Systems (MCS). These innovations in HPC technology are essential for achieving full competitiveness for heavy-duty electric transport, aviation, and maritime sectors against traditional fossil fuels.

Abstract
Efficient irrigation-water allocation remains a critical pillar of climate-resilient agricultural development, particularly in Rwanda, where more than two-thirds of the population depends on rain-fed production. To advance national targets outlined in the Irrigation Master Plan (2020) and the Rwanda Water Resources Board Strategy (2022–2027), this study developed a multi-constraint linear optimization model to allocate irrigation water among eleven major crops, utilizing five years of agricultural data (2019–2024). The model incorporated three water-availability scenarios (100%, 80%, and 60%), ecological flow requirements, FAO-56 yield response factors (Ky), and minimum area thresholds for staple crops. The study employed a rigorous statistical assessment of Linear Programming (LP) with coefficients of determination (R^2) ranging from 0.69 to 0.94, and Principal Component Analysis (PCA), which explained 77.5% of the total variance in the first two principal components. Ky ($\beta = +0.74$) most strongly explained variation in deficit-irrigation levels. At 100% and 80% national water availability, the model maximizes profits to 490.2 million USD and 376.2 million USD, using 1.84 and 1.46 billion m^3 of water, respectively. The study concluded that a linear optimization model provides a transparent and quantitatively robust decision-support tool for achieving the targets set in irrigation planning in Rwanda.
Keywords: Rwanda, irrigation, linear programming, biophysical determinants, major crops.

Introduction

Agriculture remains the backbone of Rwanda's economy (Nzeyimana et al., 2024), employing 70 percent of the workforce and contributing 33 percent to GDP (Sunday et al., 2024). Despite its significance, the sector faces challenges, including dependence on rainfall, fragmented landholdings, steep terrain, and climate variability. About water resources in Rwanda, with only 9 km^3 of renewable freshwater available annually (Nibagwire & Drouiche, 2017), and increasing competition from urban and industrial sectors, irrigation has become essential for sustainable agricultural intensification (MINAGRI, 2020). Consequently, government agencies are prioritizing the expansion and optimization of irrigation systems to enhance resilience and productivity (Chandra et al., 2023). In Rwanda, freshwater ecosystems cover about 15% of the country (Nzarora et al., 2024) with uneven distribution of water regarding space, time, and quality (Kifle Arsiso et al., 2017).

Water allocation based on historical cropping patterns or political considerations often results in inefficiencies (Ryan & Sudarshan, 2022; Browne & Ji, 2023). UN-Water (2024) defines water allocation as who receives water, when, and under what conditions. Water reallocation during shortages is essential for enhancing resilience in drought-prone basins (Alfredo & Russo, 2017). Allocation systems distribute permits or property rights that determine access, withdrawal, and use of water (Wang et al., 2018). In the case of Rwanda, to support basic natural resource and ecological functioning, water must be allocated efficiently across competing uses (RWFA, 2019).

Linear programming (LP) offers a rational and transparent framework for optimizing scarce resources (Hillier & Lieberman, 1995). In irrigation planning, LP is used to determine cropping patterns that maximize total profit and minimize water use, subject to constraints on land, labour, and water availability (Mizyed, 2025; Sadati et al., 2014), for countries like Rwanda, which aim to expand irrigated land to over 100,000 hectares by 2030 (RWB, 2020). LP models simplify computation and enable scalable analysis (Park et al., 2017). When decisions involve discrete choices—such as whether to irrigate a field—mixed-integer linear programming (MILP) is employed (Gong et al., 2020). Linear programming has been applied to optimize irrigation water allocation and reduce energy consumption, as demonstrated by Zhang et al. (2022). First application of LP to irrigation water allocation, demonstrated a 27% increase in profit through optimal redistribution of limited water among crops (Frizzone et al., 1997). Since then, LP applications have expanded to multi-crop systems, basin-level management, and irrigation scheduling under uncertainty (Gong et al., 2020). Researchers used LP in Ethiopia to allocate cropland for smallholder households (Mellaku et al., 2018). LP counted 10–30% of evapotranspiration (ET) deficits to enhance water productivity in Ethiopia (Simegn, 2019). Different studies reported that crops responded uniquely to irrigation deficit, including tomato (Boari et al., 2016), wheat (Bayisa et al., 2024), cotton (Xu et al., 2024), rice (Sedighkia & Datta, 2025), maize (Zou et al., 2021), potato (Niu et al., 2024). Optimizing irrigation in multi-crop systems requires precise modelling of crop coefficients (Kc), crop evapotranspiration (ETc), and yield response factors (Ky), as outlined in FAO-56 guidelines (Allen et al., 1998). In regions lacking local evapotranspiration (ET) data, the water footprint (WF) approach offers global coefficients for blue and green water use per unit of

crop yield (Mekonnen & Hoekstra, 2011).

LP is integrated with modern computational tools such as LINGO (Afshar et al., 2007), GAMS (Silori & Khanam, 2018), MATLAB (Fei et al., 2022) and Python's PuLP (Vinten et al., 2017) to enhance the applicability. Multivariate techniques such as scatterplots, correlation matrices, and principal component analysis (PCA) reveal structural relationships within agronomic datasets that influence optimal land and water allocation (Abdelghany et al., 2025).

Previous studies in Rwanda have focused on single crops or localized irrigation schemes. Consequently, a comprehensive national optimization covering all major crops has not yet been published. This research aims to compile a unified dataset for Rwanda's eleven key crops, apply a linear profit-maximization model under three water-availability scenarios, and analyse how crop area, water use, and national profit respond to scarcity. This study also has significant implications for the agriculture domain, where agriculture is both a cause and a victim of water scarcity. The results may serve as a resource for sectoral water allocation plans to ensure equitable sharing of water resources at the regional scale. It will also provide a policy-ready, quantitative basis for irrigation planning.

Materials and Methods

Detailed Description of the Study Area

This study was conducted in Rwanda, which lies between latitudes 1° and 3° S and longitudes 29° and 31° E. Rwanda covered 26,338 km² and ranged in elevation from 900 m in the east to more than 2,500 m in the northwest highlands. The major crops in Rwanda are beans, bananas, maize, cassava, sweet potatoes, Irish potatoes, sorghum, soybeans, vegetables, paddy rice, groundnuts, peas, fruits, and wheat crop, cultivated in seasons A (September-February) and season B (March-June). Beans are the first crop cultivated on a large scale, with 342,418.3 ha, with corresponding production of 234,027 tons. During 2024, agriculture contributes to climate resilience interventions by farming practices of 142,318.7 ha and 1031,282.8 ha of radical and progressive terraces (MINAGRI, 2024). Irrigation is leading in consumptive water use in Rwanda. The country's irrigation potential area is 600,000 ha (Mabhaudhi et al., 2025). Out of this area, 13.8% (or 72,913 ha) is already developed, including 37,273 ha for marshland, 9,439 ha for hillside irrigation, and 26,201 ha for small-scale irrigation technology (SSIT).

Rwanda has a bimodal rainfall pattern, with rainfall ranging from 1,000 to 1,600 mm, falling between September-January and February-June. Renewable water resources are about 6.80 billion m^3 per year. However, Rwanda has 670 m^3 per capita (Hakiruwizera et al., 2022), which means not rich in renewable water resources compared to the water threshold value of 1,700 m^3 per inhabitant per year (Zhong et al., 2023). Rwanda accounts for forty lakes with an estimated storage capacity of 225.2 billion m^3. Lake Kivu is the largest, with 222.33 billion m^3, and about 1000 km^2 (42%) belongs to Rwanda (RWB, 2020). Besides that, a total of 250 islands representing 315 km^2 are present in Kivu Lake. However, the previous studies indicated that the Kivu Lake zone has lost over 346,000 ha of forest cover during the period of 13 years from 1988 to 2011, due to farming activities and animal rearing (Uwamahoro et al., 2024). Rwanda accounts for fifty water storage dams with a total storage capacity of 72563,300 m^3, including 45 dams used for irrigation, 2 dams for hydropower, 2 dams for water supply, and one is used for both irrigation and water supply. Table 1 provides a summary of the key characteristics of the top ten irrigation dams (RWB, 2023). Domestic water use is the second-highest water consumption, with 38.61% (234.8 million m^3 per year). Followed by mining, industries, fishponds, and coffee washing stations with 0.79%, 0.53%, 0.17%, and 0.4%, respectively (Hakiruwizera et al., 2022).

Table 1

Classification of dams by type, height, storage capacity, and their uses in Rwanda

Name	Location	Dam type	Height, m	Storage, m^3
Rwinkwavu	Kayonza	Earth fill	9.5	4200,000
Rwangingo	Gatsibo	Earth fill	10	3750,000
Gacaca	Kayonza	Earth fill	9.5	2500,000
Muyanza	Rulindo	Earth fill	26	2300,000
Nyanza 23	Nyanza	Earth fill	19	1820,000
Kayonza-4	Kayonza	Earth fill	9.5	1600,000
Gatinga	Kayonza	Earth fill	-	1500,000
Rugende	Rwamagana- Gasabo	Earth fill	13.5	1350,000
Rwamagana-34	Rwamagana	Earth fill	14	1000,000
Cyili	Huye	Earth fill	9.5	950,000

Data sources and parameter compilation

This study uses multi-crop optimization in Rwanda because of its varied agro-ecological zones, which support perennial crops, cereals, legumes, and roots. To allow reallocation among 11 major crops, including maize, sorghum, rice, wheat, cassava, Irish potatoes,

bananas, dry beans, peas, groundnuts, and soybeans, the study's scope includes all the country's irrigated land. Ecological flow (m³) was designed for scenarios where environmental protections are guided by nationally documented policies, such as the Irrigation Master Plan. Cultivated area and yields data were derived from the agricultural seasonal survey of seasons A (September-February) and B (March-June), which was compiled by the National Institute of Statistics of Rwanda (NISR, 2022). Water footprint, WF (m³ kg⁻¹), refers to the blue-green water footprint per crop from 1996-2005. Water per hectare (m³ ha⁻¹) collected by following the methodology of Allen et al. (1998) and calculated as yield × 1000 × WF. Producer prices (USD t⁻¹) were adapted from the farm-gate price built by the FAOSTAT producer domain (Vos et al., 2023). Water availability (m³) was referred to the national annual envelope of irrigation water at 100%; scenarios scale this by 80% and 60% to represent drought stress (RAB, 2010). In addition, yield-response factors (Ky) follow FAO-56 guidelines. Seasonal yield-response factors, Ky, represent the linear effect of deficit irrigation (Allen et al., 1998).

Model Optimization

The study developed a linear programming model that includes four constraints and uses McCormick linearization to maintain linearity (Leyffer & Manns, 2025), while enabling continuous deficit irrigation decisions for each crop (Table 2). The study used Python's PuLP algorithm to enhance the applicability of LP models. Multivariate techniques, including scatterplots, correlation matrices, and principal component analysis (PCA), were used to validate the structural relationships within agronomic datasets that influence optimal land and water allocation.

Table 2

Set and definitions of variables

Variables	Definition of variables
$\mathcal{C}$	Crops (11), including maize, sorghum, rice, wheat, cassava, Irish potatoes, bananas, dry beans, peas, groundnuts, and soybeans
A_c	Irrigated area of the crop c (ha), noted by Area_cap_ha, and it should be positive
x_c	Deficit level (fraction of full irrigation), applied to the crop c, nd varies between $[0,1]$
Z_c	Linearization of water and yield variables($A_c x_c$). It should be positive
$Y_c(x_c)$	Yield and revenue under deficit linear terms ($Y_c(x_c)$, using FAO-56 $K_y$response, the per-hectare yield under deficit
$K_{y,c}$	Yield response factor for 11 crops
Y_c^{pot}	Five years Average of yields 11 crops at full irrigation (t ha⁻¹).
W_c^{full}	Linearization of water accounting with full-irrigation water requirement per hectare (m³ ha⁻¹),
$x_c W_c^{full}$	Under deficit x_c, water per hectare, (m³ ha⁻¹)
P_c	Producer price revenue (USD t⁻¹).
C_c	Per-hectare cost (USD ha⁻¹).)
s	Water availability scenarios (100%, 80%, and 60%)

Objective functions

Application of a linear profit-maximization model for water-availability scenarios has aimed to analyze how crop area, water use, and national profit respond to scarcity as in Equation 1.

$$\text{Max} \sum_{c \in \mathcal{C}} [\underbrace{\left(P_c Y_c^{\text{pot}} - C_c - P_c Y_c^{\text{pot}} K_{y,c}\right)}_{\text{coefficient of } A_c} A_c + \underbrace{\left(P_c Y_c^{\text{pot}} K_{y,c}\right)}_{\text{coefficient of } Z_c} Z_c] \quad (1)$$

Formulation of the Constraints

Equation 2 illustrates water availability with ecological reservation.

$$\sum_c Z_c W_c^{\text{full}} \leq s \cdot W^{total} - \text{Eco Flow} \quad (2)$$

Under scenarios, total water use should not exceed the amount of water available (by scenario $s \in \{1.0,0.8,0.6\}$).

Equation 3 indicates the cultivated area limitations.

$$\sum_{c \in C} A_c \leq A^{total} \quad (3)$$

The total adjacent area should not exceed the usable agricultural land limit.

Minimum cultivated area constraints for staple crops under the food safety policy (Equation 4).

$$A_c \geq \bar{A}_c \text{ for } c \in \{\text{maize,beans,cassava}\} \quad (4)$$

All constraints should be positive as McCormick envelopes (Equations 5-8).

$$Z_c \leq A_c, \quad (5)$$

$$Z_c \leq \bar{A}_c \, x_c \quad (6)$$

$$Z_c \geq A_c - \bar{A}_c(1 - x_c) \quad (7)$$

$$Z_c \geq 0. \quad (8)$$

These four linear inequalities exactly bound the bilinear term on the $[0, \bar{A}_c] \times [0,1]$ rectangle and deficit feasibility boundaries $[0 \leq x_c \leq 1, 0 \leq A_c \leq \bar{A}_c]$.

Statistical Analysis

A statistical methodology deployed to assess if the linear optimization model is internally consistent and has implications in real field agronomy. Both the Standardized regression (β) analysis, the regression model of determination of coefficient (R^2), and the correlation matrix were analysed. A principal component analysis (PCA) was also used in the exploration of the data. Scatterplots were useful for observing linear and non-linear relationships, with evident crop groups such as cereals, legumes, and tubers.

Results and Discussion

Under full irrigation (100% water availability), the optimization model allocates land to maximize national profit, which reaches $490.2 million, using 1.84 billion m³ of water. When water availability drops to 80%, national profit declines to 376.2 million USD, and total water use falls to 1.46 billion m³, prompting a more conservative allocation. Under severe scarcity (60% availability), the system undergoes a dramatic restructuring, with national profit dropping to $262.6.0 million USD and water use decreasing to 1.13 billion m³ (Table 3). Cassava stands out for its drought tolerance and high caloric output, while potato provides stable yields on volcanic high plateaus; these findings are consistent with studies in SSA and East Africa (Nweke, 2004). In contrast, rice and beans have a high-water footprint, with optimization studies emphasizing their opportunity costs (Bouman & Tuong, 2001). Cassava dominates due to its low Ky value and high caloric output, while potato benefits from favourable physiology and high farm-gate prices (Kiziloglu et al., 2006; Badr et al., 2022). Rice and beans, however, show limited growth due to their high-water footprint and stress sensitivity, consistent with findings in the optimization literature (Bakhsh et al., 2024; Rathore & Pandey, 2023). Under moderate scarcity, cassava, potato, and banana maintain dominance, whereas rice and beans contract sharply (Zwart & Bastiaanssen, 2004). Under extreme scarcity, the model prioritizes drought-tolerant crops to ensure optimal water resource utilization.

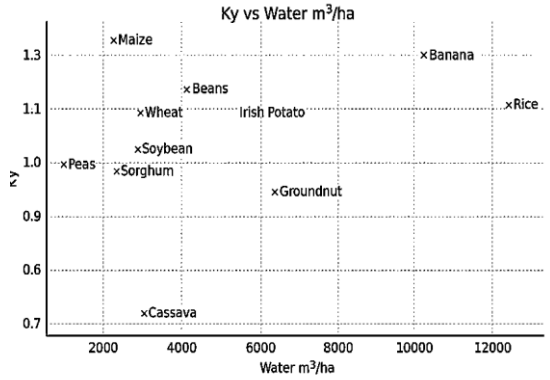
Table 3

LP model for crop area allocation under water availability scenario and profitability

Crop	Allocate area (ha) by water availability scenario			Profit (USD Million) by scenario		
	100%	80%	60%	100%	80%	60%
Cassava	180,000	165,000	150,000	112.4	89.7	64.5
Irish Potato	165,000	150,000	124,000	154.9	113.2	79.8
Banana	140,000	126,000	110,000	97.5	82.5	63.2
Soybean	75,000	60,000	42,000	33.6	24.8	15.6
Groundnut	62,000	48,000	32,000	27.4	19.3	11
Maize	50,000	50,000	50,000	21.5	18.4	13.5
Beans	60,000	60,000	60,000	15.9	11.1	6.2
Peas	25,000	18,000	11,000	8.7	5.2	2.8
Sorghum	18,000	14,000	10,000	6.3	4.7	2.4
Wheat	15,000	11,000	8,000	7.8	5.4	3.1
Rice	8,500	4,200	1,200	4.2	1.9	0.5
Total	798,500.0	706,200.0	598,200.0	490.20	376.20	262.60

The integrated analysis of Rwanda's LP-optimized irrigation model, using averaged national data from 2019–2024, reveals a clear biophysical and economic logic behind crop prioritization across 11 major crops. The model processed a total feasible irrigable base of 798,500 ha, with yields ranging from 1.1 t ha^{-1} (beans) to 18.5 t ha^{-1} (Irish potato) and water requirements from 2,900 m³ ha^{-1} (cassava) to 14,200 m³ ha^{-1} (rice).

LP model allocated area, profitability, water-use efficiency, deficit irrigation resilience, and performance stability by ranking as 1st Irish potato, 2nd Cassava, 3rd Banana, 4th Soybean, 5th Groundnut, 6th Maize, 7th Beans, 8th Peas, 9th Sorghum, 10th Wheat, and 11th Rice.



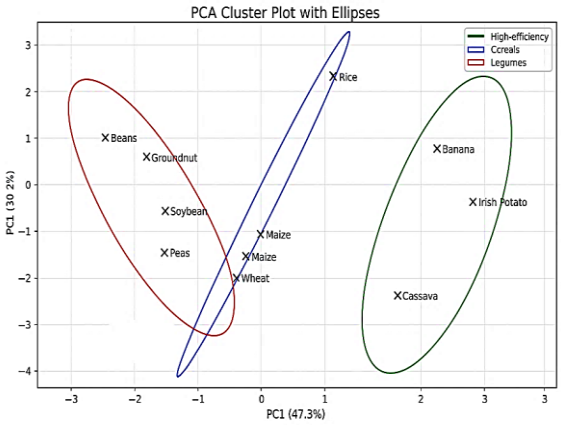
Irish potato leads due to its high yield (18.5 t ha^{-1}), strong market value, and moderate water needs, contributing $97.5–154.9 million annually with a Ky of ~1.1. Irish potatoes have shown resilience even at 60% water availability. Cassava follows, valued for its drought tolerance, low water footprint (3300 m³ ha^{-1}), and stable profits ($64.5–112.4 million), supported by its low Ky (~0.7). The model considers bananas as a fixed crop due to its perennial nature and profits between $63.2–97.5 million per season, despite a higher water footprint. Peas, sorghum, and wheat offer niche returns, while rice ranks last due to its high-water footprint (12,750 m³ ha^{-1}), cost, and Ky sensitivity, contributing only $0.5–4.2 million. This ranking was

validated statistically via PCA and regression diagnostics, confirming that Rwanda's LP-optimized crop prioritization is grounded in biophysical and economic realities.

Figure 1 illustrates the water use by crop response factor (Ky), crops like cassava, banana, and Irish potato tolerate moderate to high deficits with minimal yield loss due to their low Ky value, consistent with FAO-56 findings that lower Ky correlates with reduced sensitivity to water stress (Allen et al., 2004). This enables the model to apply strategic water-saving measures while maintaining profitability, especially for resilient, high-efficiency crops. In contrast, maize and beans exhibit high sensitivity to deficit irrigation, with elevated Ky values causing steep yield declines even under slight water reductions (Ma et al., 2023). Consequently, the model reduces the area allocated to these crops rather than subjecting them to high deficits, like optimization studies from India (Srilatha et al., 2022), Indonesia (Hidayat et al., 2023). The LP model revealed that when water availability drops to 80% and 60%, agricultural water use also decreases, but not linearly, indicating a strategic shift toward high water-productivity crops like cassava, Irish potato, and banana.

Figure 1

Allocation of water use by crop response factors



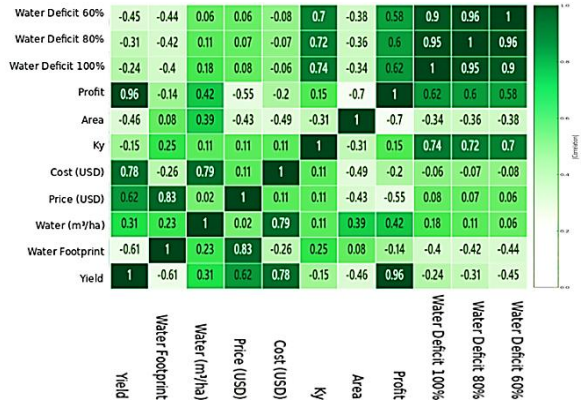
Standardized regression (β) analysis confirms three LP outcomes of optimized area, profit, and deficit response as follows: yield is the strongest positive predictor of land allocation (β = 0.71), while water footprint is the strongest negative (β = –0.64). Profit is the strongest predictor of price and yields, with β of 0.82 and β = 0.55, respectively, as key drivers. While water footprint again reduces profitability (β = –0.47). Ky factor (β = 0.74) is the dominant predictor of deficit-irrigation response, validating the model's sensitivity to crop stress tolerance. These findings collectively reinforce the LP model's structural logic, showing that multi-dimensional biophysical and economic traits are essential for sustainable irrigation planning in Rwanda.

Figure 2 illustrates the Principal Component Analysis (PCA) scatter plot, which explains 77.5% of the total variance across the first two principal components (PC1 and PC2). PC1 visualized crop clustering with 47.3% variance. This PC1 separates crops by yield and water footprint. It places cassava, Irish potato, and banana in a high-efficiency cluster. In contrast, PC1 places rice, beans, and groundnuts into a low-efficiency group. PC2 of 30.2% variance visualizes economic traits. PC2 indicated that rice has a high-price/high-cost extreme. However, cassava is at the low-cost/high-yield end. PCA indicates that cereals such as maize, wheat, and sorghum cluster near the origin, reflecting moderate biophysical traits and sensitivity to water constraints.

Standardized regression (β) analysis confirms three LP outcomes of optimized area, profit, and deficit response as follows: yield is the strongest positive predictor of land allocation (β = 0.71), while water footprint is the strongest negative (β = –0.64). Profit is the strongest predictor of price and yields, with β of 0.82 and β = 0.55, respectively, as key drivers. While water footprint again reduces profitability (β = –0.47). Ky factor (β = 0.74) is the dominant predictor of deficit-irrigation response, validating the model's sensitivity to crop stress tolerance. These findings collectively reinforce the LP model's structural logic, showing that multi-dimensional biophysical and economic traits are essential for sustainable irrigation planning in Rwanda.

Figure 2

Principal Component Analysis scatters plot of major crops



The coefficient (R^2) results provided robust evidence that the linear programming (LP) model behaves realistically. Predicted values for profit, land allocation, and deficit-irrigation responses closely matched the observed patterns. Economic variables, especially yield and market price, played the largest role, accounting for about (R^2 = 84%) of the variation in optimized profit and 78% of the variation in how land was allocated. In contrast, water footprint consistently reduced both profit and the area assigned to each crop. The response to deficit irrigation showed more biological complexity but remained predictable; the yield response factor (Ky) emerged as the strongest single driver (R^2 = 0.74), and when combined with

water footprint and price, explained (R^2 = 70%) of the overall variation. Altogether, these findings show that LP optimization is realistic in agronomic and economic relationships. Figure 3 highlights relationships among the key variables by correlation matrix analysis. Yield shows a strong negative correlation with water footprint (r = –0.61), reinforcing the idea that higher-yielding crops typically use water more efficiently. Water footprint, however, is strongly and positively correlated with price (r = +0.83), suggesting that crops requiring more water are often high value but less practical when water is limited.

Figure 3

Correlation matrix analysis

Land allocation also follows a logical pattern: it increases with yield (r = 0.84–0.86) and decreases as water footprint rises (r = –0.45 to –0.46). Deficit levels are negatively related to both profit and cultivated area, particularly in the 60% water-availability scenario, where correlations reach r = –0.62 to –0.64 for profit and r = –0.59 to –0.70 for area.

Across all scenarios, profit maintains strong correlations with both yield and optimized land area (r > 0.90), reflecting consistent crop performance within the optimization framework.

Conclusions

1. The findings indicate that the LP model serves as an analytical decision-support tool that informs decision-makers on optimal irrigation water allocation across eleven major crops in Rwanda.
2. Study found that crops like cassava, Irish potato, and banana perform best under full irrigation, while water-demanding crops lose land.
3. When water is scarce, the system shifts toward drought-tolerant crops and uses deficit irrigation to stay efficient.
4. Good water management needs strong coordination across environmental, agricultural, and water-related sectors.
5. Future research should explore digital storage, groundwater recharge, and reservoir strategies to improve sustainable and fair water allocation.

BELL PEPPER RESPONSE TO MULCH TYPES UNDER DIFFERENT IRRIGATION STRATEGIES

Emmanuel Hakiruwizera[1,2], *Yusuf Ucar[1]

Abstract
Water shortages and competition for irrigation water demand strong measures to cope with the needs in an efficient manner. Therefore, this work investigated the impact of plastic mulching and organic mulching on bell pepper production under both deficit- and full-irrigation regimes, particularly in the Southern Province of Rwanda. The field experiment was designed as a split-plot combined with a Randomized Complete Block Design (RCBD). The study set the main plots as irrigation levels (100% and 50% of crop evapotranspiration), while subplots represented mulching types (organic and plastic), with three replications. The soil moisture sensors with profile probes were installed in the experimental field to monitor the daily depletion of soil moisture. Results showed that the total water requirements for organic mulch (OI_{100}) and plastic mulch with full irrigation (P_{I100}) were 420.4 mm and 390 mm, respectively. In OI_{100}, the treatment with organic mulch yielded the highest fresh fruit yield at 58.5 t ha^{-1}, while the highest dry matter yields were reached with organic mulch and 50% deficit irrigation (OI_{50}), at 765.4 kg ha^{-1}. Organic mulching with full irrigation produced the best yield, surpassing plastic mulch with full irrigation. Compared to organic grass-clipping mulch, plastic mulch maintained 6% to 24% higher soil moisture content. Consequently, it saved between 7.8% and 18% of irrigation water under full and deficit irrigation conditions, respectively. Building on previous research, both plastic and organic mulches provide various benefits to the soil and bell pepper crops.
Keywords: crop water requirement, deficit irrigation, organic mulch, plastic mulch.

Introduction

Water scarcity and increasing competition for irrigation resources demand effective strategies to improve water-use efficiency. The widely adopted irrigation strategy used to minimize irrigation water use is deficit irrigation without compromising crop yields, thereby improving water use efficiency (Demo & Tsehai, 2024). This method enhances water productivity without inducing water stress or drought conditions (Mardani et al., 2017). Bell pepper is recognized as a high-value crop with significant income both locally and on a global scale. It is consumed fresh or cooked in a variety of dishes (Truong et al., 2025). Rich in nutritional compounds of vitamins A, C, and E, phenolics, as well as capsaicinoids, bell pepper offers notable antioxidant and health benefits (Alonso-Villegas et al., 2023). Despite progress in breeding and genomic research aimed at improving traits like fruit development and capsaicin production, the phylogenetic relationships within *C. annuum* remain underexplored. Originating from Mesoamerica, particularly Mexico - *C. annuum* exhibits broad environmental adaptability (De la Cruz-Ricardez et al., 2024). Bell pepper presents promising opportunities for small-scale farmers and food innovation (Van Zonneveld et al., 2015). Environmental and developmental factors also influence the synthesis of bioactive compounds in bell pepper, affecting its nutritional quality. However, bell pepper production is often limited by suboptimal temperature conditions. Agronomic practices such as polyhouse cultivation, black plastic mulching, and adjusted planting dates have been shown to improve early and total yields in regions with unfavorable temperatures (Dhaliwal et al., 2017). As one of the top contributors to the horticultural economy (Carvalho et al., 2023), bell pepper cultivation benefits significantly from water-saving practices. Previous studies reported that mulching techniques improve soil moisture holding capacity and reduce erosion, as well as regulate soil temperature in drought-prone areas (Ramakrishna et al., 2006). Research confirms that mulching enhances plant growth and yield due to its capture of soil loss and water use efficiency (Bijalwan et al., 2022). Nevertheless, the combined application of irrigation and mulching remains underrepresented in scientific literature. Plastic mulching is widely used for soil warming, weed suppression, and yield quality improvement. However, concerns persist regarding the environmental impact of non-biodegradable plastics (Guerra et al., 2024).

Colak (2021) announced that bell pepper requires intensive monitoring of water management to reduce the drop in yields. The study proposed drip irrigation as a technique to optimize water use and enhance crop productivity. Both excessive and insufficient water stress can significantly affect plant growth and yield (Menezes et al., 2024).

Therefore, this study aims to evaluate in the field the effect of different irrigation strategies combined with mulching practices on the response of bell pepper, with a focus on optimizing water use and improving irrigation scheduling. It seeks to monitor soil moisture dynamics for precise irrigation planning, determine crop water requirements, and estimate seasonal evapotranspiration. This case study was conducted in Huye District, Rwanda, where dry season conditions limit pepper production, and water deficiency adversely affects flowering and yield.

Materials and Methods

The field experiment was conducted at the Rwanda Polytechnic Huye College research center, located in Huye District (2°36'37" S, 29°43'59" E). Huye district

has an average altitude of 1,700 m, a mean annual temperature of 20 °C, and an annual rainfall of 1,150 mm (Dahlin et al., 2021). The climate is sub-equatorial temperate, and agriculture is traditional with limited mechanization. At the national level, irrigated land in the district includes 1,740 ha of marshland and 81 ha of hillside irrigation (Hakiruwizera et al., 2024).

Variety California Wonder-PP2285-05B, sourced from Holland, was used. Plants were spaced 40 cm apart with 50 cm between rows, resulting in a population density of 50,000 plants per hectare. Nursery planting began on April 26, 2024, with transplanting performed one month after each nursery establishment. The maximum root depth ranges from 0.3 to 0.6 m (Waller & Yitayew, 2016). Sweet peppers have an allowable soil moisture depletion (p) of 0.30 (Bozkurt Çolak et al., 2023). Bell peppers grow optimally at temperatures between 21 and 24 degrees Celsius. However, it tolerates a temperature of less than 18 °C and a maximum of 26 °C. Fertilization at planting included 600 kg ha^{-1} of 2:3:4 NPK.

Bulk density for 30 cm soil depth was 1.49 g cm^{-3} and 1.51 g cm^{-3} at 60 cm soil depth. Field capacity was 22.2%, permanent wilting point 14%, and soil texture was sandy loam. Saturation content was 43.3%, hydraulic conductivity 22 mm h^{-1}, and organic matter content 3.3% at 30 cm depth and 2.4% at 60 cm.

A drip irrigation system is used to supply water to the plots. Pressurized water was pumped into a 10 m^3 storage tank elevated 3 m above the field, then distributed by gravity through a 32 mm main pipe and four 25 mm submains. Each submain supplied three 16 mm driplines, totaling 36 driplines with emitters discharging 2 L h^{-1}. Screen filters ensure water quality. Each treatment plot measured 1.4 m × 10 m with 1 m spacing. The experimental area covered 308 m^2. Soil moisture was monitored with eight profile probe sensors. The experiment used a split-plot design within a randomized complete block design. Irrigation levels were the main plots, and mulching types were subplots with three replications. Irrigation treatments were full irrigation at 100% field capacity and deficit irrigation set at 50% field capacity. Mulching treatments included a black polyethylene sheet and organic grass clippings. Treatments: OI_{100} (organic mulch + full irrigation), PI_{100} (plastic mulch + full irrigation), OI_{50} (organic mulch + deficit irrigation), PI_{50} (plastic mulch + deficit irrigation). No stress was imposed during germination. The study adapted the soil-water balance approach to monitor the frequency of irrigation scheduling.

Soil water depletion (Dc) was calculated daily using the method (Allen et al., 1998). During the experiment, soil moisture content was measured using a hand-held moisture meter (HH2) connected to profile probe sensors (PR2), with data recorded in Excel (Marković et al., 2024). The irrigation threshold was 30% water depletion. The difference between field capacity and the current soil water level determines net irrigation. Seasonal irrigation requirements were obtained as the sum of all irrigation events. Crop evapotranspiration was calculated as Allen et al. (1998), ETc = ETo × Kc × Ks, where ETo stands for reference evapotranspiration, Kc for the crop coefficient, and Ks for the water stress coefficient (1 for full irrigation, less 1 under deficit irrigation).

Yield and yield parameters were monitored during the season. Plant height was observed weekly from three weeks after transplanting on five plants per plot. Nodes were counted at harvest. Yield was measured from a 1 m^2 area, weighing marketable and non-marketable fruits. Pericarp thickness was measured on vine-ripened fruits with a vernier caliper. Fruits' dry matter was determined after drying at a temperature of 65 °C. Fruit number per plant and fruit length were measured on four plants/fruits per plot. ANOVA was performed using Minitab 17. LSD Fisher test with $p = 0.05$ compared treatment means for yield parameters, and OriginPro software is used to generate graphs.

Results and Discussion

Black plastic-mulch maintained soil moisture between 6% and 24% under full and deficit irrigation, respectively. Plastic mulch delayed moisture depletion and reduced irrigation frequency, consistent with El-Beltagi et al. (2022). These results confirm plastic mulch as a promising practice for deficit irrigation management. The crop season lasted 121 days. Effective rainfall contributed only 13.6 mm. Net irrigation under full irrigation was 376.4 mm (plastic mulch) and 406.8 mm (organic mulch). Under deficit irrigation, 262 mm and 313.3 mm were applied, respectively. Seasonal crop water requirements were 390 mm and 420.4 mm under full irrigation and 275.6 mm and 326.9 mm under deficit irrigation (plastic and organic mulch, respectively) (Figure 1). Plastic mulch saved 7.8%–18% irrigation water compared to organic mulch. Different irrigation regimes, mulching type, and interactions were significantly different and affected yield parameters ($p < 0.05$), except for nodes per plant. Fresh weight ranged from 12.2 t ha^{-1} (PI_{50}) to 58.5 t ha^{-1} (OI_{100}). Dry yield ranged from 0.35 t ha^{-1} (PI_{100}) to 0.76 t ha^{-1} (OI_{50}). Fruit numbers ranged from 5.5 per plant (PI_{50}) to 8.8 per plant (OI_{100}). Fruit length ranged from 4.4 cm (PI_{50}) to 7.5 cm (OI_{100}), as illustrated in Table 1. Organic mulch with full irrigation achieved the highest yield performance, while plastic mulch under deficit irrigation performed the poorest (Figure 2). The results observed were aligned, as reported by (Rocha et al., 2025) and (Asif et al., 2016). The study observed that plastic mulch conserves water but may reduce yield potential under stress, whereas organic mulch maximizes yield under optimal irrigation. Higher dry matter yield under OI_{50} suggests moderate stress enhances fruit solids, beneficial for processing (Candido et al., 2009). Rocha et al. (2018) demonstrated that drip irrigation at 50% of ETc combined with mulching produced 42.15 t ha^{-1} and the highest water use efficiency (148.99 kg ha^{-1}

mm^{-1}). Similarly, our results under OI_{50} showed improved dry matter content, suggesting that controlled deficit irrigation with mulching can optimize quality traits even under reduced water supply.

Figure 1

Seasonal irrigation requirements under different mulch and irrigation treatments

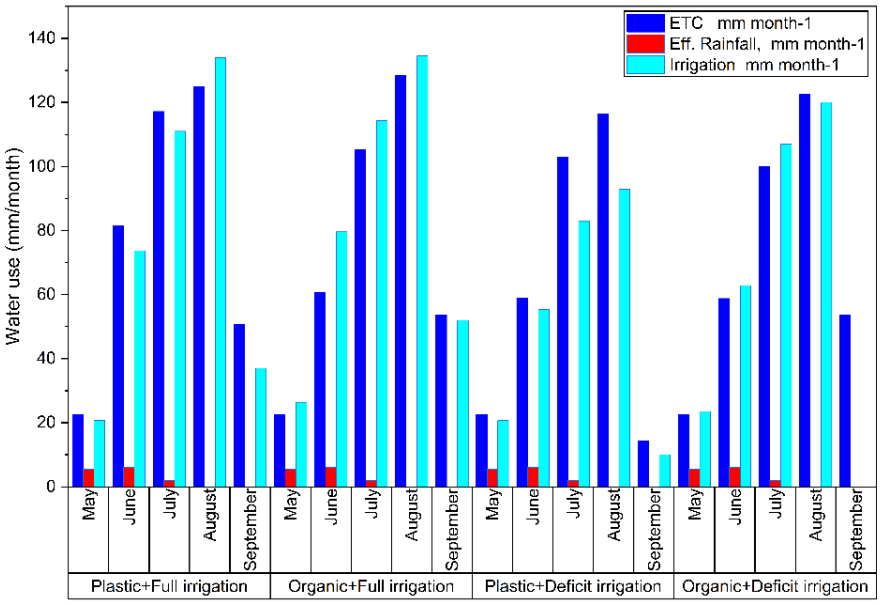

Table 1

ANOVA results and treatment mean for the yield components of bell pepper for two seasons

Treatments	Fresh weight t ha^{-1}	Dry matter yield t ha^{-1}	Number of fruit $plants^{-1}$	Fruit length, cm	Number of nodes $plant^{-1}$
Effect of main plots: Irrigation					
I100	45.5 ± 2a	0.4 ± 0.03b	7.96 ± 0.3a	6.89 ± 0.3a	6.20 ± 0.2
I50	16.1 ± 1.9b	0.7 ± 0.02a	5.93 ± 0.3b	5.24 ± 0.2b	6.17 ± 0.2
Effect of sub-plot: Mulching type					
O	39.3 ± 2a	0.6 ± 0.03a	7.56 ± 0.33a	6.78 ± 0.3a	6.35 ± 0.2
P	22.4 ± 1.9b	0.5 ± 0.02b	6.33 ± 0.3b	5.34 ± 0.2b	6.03 ± 0.2
Interactions: Irrigation x mulching

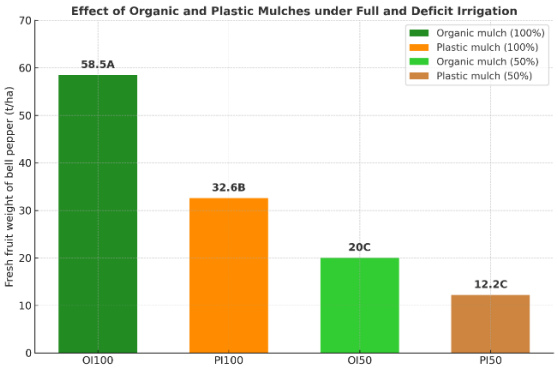
PI50	12.2 ± 1.4	0.61 ± 0.04	5.53 ± 0.4	4.47 ± 0.4c	6.00 ± 0.2



Different lowercase letters (a, b, c) show statistically significant differences ($p < 0.05$).

Mateille et al. (2020) further highlighted the disease suppression benefits of mulching when combined with tobacco waste, while Bijalwan et al. (2022) reported that combining mulch with growth regulators (NAA) boosted yield to 38.5 t ha^{-1}. Our study complements these by showing that organic mulch with full irrigation not only enhances yield but may also improve crop health through soil fertility benefits.

Varietal responses under mulching emphasize that mulching benefits extend across genetic lines, which aligns with the robust performance of organic mulch treatments in our trial (Valšíková-Frey et al., 2022). Likewise, Candido et al. (2009) confirmed that full irrigation (100% ETc) combined with balanced nitrogen fertilization produced the maximum yield (72 t ha^{-1}), whereas late-season stress reduced yields by 44%. This parallels our observation that deficit irrigation under PI50 was severely limited despite water savings.

Figure 2

Effect of organic and plastic mulches under full and deficit irrigation

Note: Different letters (A, B) show statistically significant differences ($p < 0.05$), while the C letter is not significantly different. I100: Full irrigation, I50: Deficit irrigation, O: Organic mulch, P: Plastic mulch.

Other studies confirm the broader environmental benefits of mulching. Neto et al. (2020) demonstrated effective weed suppression with polyethylene and biodegradable mulches, while Hernández-Aranda et al. (2021) reported that crop-residue mulch improved biomass by 84% under limited irrigation. These findings are consistent with the water-conservation benefits we observed with plastic mulch. Bozkurt Çolak et al. (2023) suggested that integrating mulching with modern irrigation technologies can further enhance water productivity and yield resilience. Together, these comparative insights reinforce the dual role of mulching for maximizing yield in water-abundant contexts (organic mulch with full irrigation) and saving water in water-limited environments (plastic mulch with deficit irrigation).

Conclusions

1. The study demonstrated that mulch type and irrigation strategy significantly influence bell pepper productivity and improve water use efficiency. Organic mulch with full irrigation produced high yield (58.5 t ha^{-1}), whereas plastic mulch achieved greater water savings (7.8%–18%) under both irrigation regimes.
2. Both Organic and plastic mulch are important in deficit irrigation and water management of bell pepper crops.
3. In the context of practical implications, plastic mulch should be prioritized in water-limited environments, while organic mulch should be adopted when maximizing yield and soil health is the goal.
4. In Huye's ecological settings, the mulching techniques take significant steps to enhance water scarcity, competition for irrigation demand, and water usage efficiency.
5. Future studies should assess the economic feasibility and environmental sustainability of these practices, particularly regarding non-biodegradable plastics.

THE POTENTIAL OF ROBOTISATION FOR STRAWBERRY CULTIVATION IN OPEN FIELDS: A REVIEW

***Artūrs Feldmanis, Vilnis Pīrs, Kārlis Banis**
Latvia University of Life Sciences and Technologies, Latvia

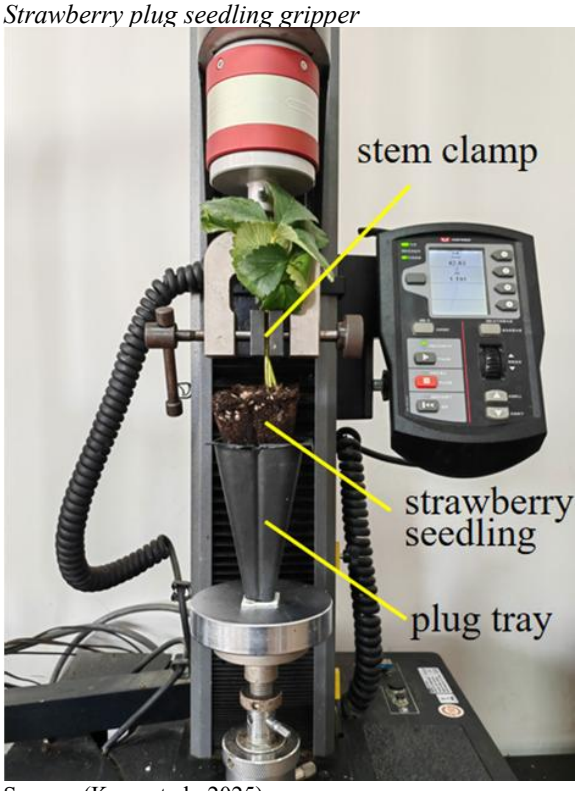
Abstract
Strawberry cultivation is one of the most labour-intensive areas of horticulture, relying heavily on manual labour. In fruit production, these costs can reach up to 60% of total production expenses. At the same time, demand for fresh, locally grown strawberries is relatively high throughout the world. There are various robotic solutions for both the establishment and maintenance of strawberry fields. Most of these solutions are designed as tractor-pulled units, but the biggest challenge is mechanized harvesting. In recent years, thanks to advances in technology and artificial intelligence, the mechanization and automation of strawberry picking has also been developing rapidly. The aim of this study is to review the development and application of robotic and automated technologies in strawberry cultivation, analyse their use across different cultivation processes, and identify future directions for robotisation in open-field systems. The study is based on an analysis of recent scientific publications in the relevant field. The results of the study identify the most important stages in the strawberry growing process where robotisation can be introduced and where additional investment in development is needed. The results indicate that several strawberry cultivation processes, particularly transplanting, irrigation management and monitoring, show strong potential for automation due to their structured and repeatable nature. More complex operations such as pruning and harvesting remain technically challenging and require further development of perception systems, manipulators and end-effectors.
Keywords: strawberry, robot, cultivation, automation, horticulture.

Introduction

The strawberry (*Fragaria × ananassa Duch*.) is one of the most widely cultivated and economically important berry crops worldwide. It is characterised by high market demand and intensive production practices. In open-field production, a significant proportion of total production costs is related to manual labour, particularly for activities such as crop monitoring, weed control, harvesting and post-harvest handling. According to Defterli et al. (2016), labour-related expenses account for a large share of overall production costs, particularly in specialty crops that require frequent and delicate manual operations. Studies suggest that labour costs can reach up to 60% of total production costs in labour-intensive agricultural sectors such as fruit production (Baraldi et al., 2007). Strawberry cultivation involves low-growing plants and a production cycle that requires frequent close-range interventions in the field throughout the growing season. As a result, many critical operations must be carried out repeatedly and with high precision, making strawberry cultivation a labour-intensive and operationally complex production system (Hancock, 2020). In addition to high manpower costs, the production of strawberries is increasingly affected by a shortage of agricultural workers, driven by factors such as urbanisation, an ageing rural workforce, and the seasonal nature of agricultural employment. These labour shortages have become a key motivator for adopting robotic and automated solutions in agriculture, particularly in work-intensive crop production systems (Anastasiou et al., 2025).

Wider reviews of the automation of agricultural machinery emphasize that the level of automation achieved varies substantially between different processes and systems in agriculture and crop production. This reflects differences in task complexity, environmental variability, and economic feasibility (Jiang et al., 2025). Consequently, despite rapid technological development, the adoption of robotic and automated solutions remains uneven across the full range of agricultural operations, highlighting the need to evaluate the technological maturity of each process specifically.

Technological progress in agricultural robotics, including autonomous ground vehicles, sensor-based systems and machine vision technologies, has enabled the automation of various field operations such as monitoring, weeding and harvesting. Further advances in sensing technologies, machine vision, and autonomous navigation have facilitated the development of robotic platforms that can operate in outdoor agricultural environments. These platforms support data-driven decision-making and reduce dependence on manual manpower in crop production. At the same time, despite significant technological progress, the maturity and adoption levels of robotic solutions vary considerably between different agricultural operations and crop types. There is a persistent gap between technological development and practical, farm-level requirements (Fontani et al., 2025). Several review studies on precision agriculture indicate that robots are most frequently used for repetitive, structured operations such as crop monitoring, weed control, planting activities and harvesting, where tasks can be clearly defined and executed with high repeatability (Comparetti et al., 2025). Such applications are commonly implemented using ground-based robotic platforms or unmanned aerial vehicles (UAVs) equipped with cameras, proximity sensors, and navigation systems, allowing continuous field operation and spatially explicit data collection. The suitability of these operations for automation has led to faster technological progress in monitoring and weed management than in other cultivation tasks.



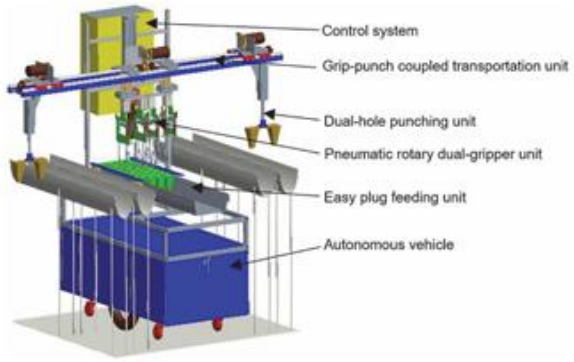
In contrast, operations requiring high selectivity, delicate manipulation, or close interaction with the crop canopy are considerably more challenging to automate. This is particularly true in unstructured open fields, where there is variable lighting, plant morphology, and environmental disturbances (Spagnuolo et al., 2025). Therefore, many robotic systems targeting such tasks remain in the prototype or experimental stage and have not yet been widely adopted commercially.
The aim of this study is to review the development and application of robotic and automated technologies in strawberry cultivation, analyse their use across different cultivation processes, and identify future directions for robotisation in open-field systems.

Materials and Methods
A literature search was conducted across multiple scientific databases, including Scopus, Web of Science, and ScienceDirect. The search and screening procedure was performed independently within each database. The initial search results were screened based on titles and abstracts, and approximately 20 articles were considered for each of the seven crop management processes. From these, up to five of the most relevant studies were selected for detailed analysis based on their focus on the development and practical implementation robotic solutions, with the most promising among them included in the study. Additional scientific publications not indexed in the aforementioned databases were also considered. The selected publications mainly included peer-reviewed journal articles and conference proceedings related to automation and robotics in strawberry cultivation.
Keywords such as ‘strawberry’, ‘automation’, ‘robot’, and ‘robotics’ were used together with terms describing specific cultivation processes. Studies where robotic solutions were tested under open-field conditions were prioritised. If such studies were not available for a particular cultivation process, research from greenhouse or indoor environments was also considered. In some cases, studies describing promising individual automation components were also included. Review articles were mainly used to provide contextual understanding and identify broader technological trends. The selected studies were analysed in terms of their practical applicability, technological maturity and potential to reduce manual labour. In instances where such data were documented, comparisons were drawn with conventional human-performed operations. The analysed publications were further grouped according to the main cultivation processes in strawberry production, including transplanting, irrigation, monitoring, mulching, weeding, pruning and harvesting.

Results and Discussion
This section presents an analysis of robotic applications across the main stages of strawberry cultivation, with technologies discussed according to individual crop management processes.

Seedling transplanting
In intensive production systems, strawberry seedlings, unlike many other crops, are grown as plug plants in specially designed trays. The seedlings have a relatively large root ball, and during transplanting it is essential to preserve its integrity. Strawberry planting is a precise but repeatable process. The work includes sequential steps such as removing the seedling from the tray, transferring it to the planting location, inserting it into the soil, and compacting the soil around the root ball. Strawberry plugs are characterized by a relatively dense and large root ball, which facilitates mechanical gripping but increases the need for precisely controlled planting depth. Transplanting is one of the processes most suitable for robotisation, as it consists of structured and repeatable stages – gripping, transferring, and precise placement. Kang et al. (2025) presented a recently developed new gripping mechanism for extracting strawberry seedlings from trays.

Figure 1
Strawberry plug seedling gripper



Source: (Kang et al., 2025).

The aim of their work was to design and optimise a strawberry seedling pick-up mechanism to preserve plug integrity. Coupled EDEM-RecurDyn simulations were performed, and three main adjustable parameters were identified – picking acceleration, needle spacing, and insertion depth – which, when modified, can improve the results. After determining the optimal parameters, field tests were carried out, and the gripping mechanism was able to ensure a high level of plug seedling integrity after extraction from the tray – 93.23%. The field test results were very close to the

simulation results, with only a 4.29% relative error between the predicted and the actual seedling integrity ratio. Kang et al. (2025) acknowledge that further research under different conditions is needed in the future, and that the developed solution should be integrated into a complete transplanter system and evaluated according to overall performance indicators. Figure 1 shows the developed gripper during testing.

A complete and autonomous transplanting system was developed and tested in elevated beds by Liu et al. (2019). The developers focused on the specific characteristics of strawberry seedlings – their increased size and the requirement for proper orientation of the plant curvature during transplanting. The developed model includes photoelectric sensor-based navigation, a rotating dual-gripper, a dual-hole punching mechanism, as well as a transport unit synchronized with both the gripper and the punching mechanism. Figure 2 shows the 3D model of the developed autonomous strawberry plug seeding transplanter. In greenhouse field tests, the robot demonstrated successful performance, transplanting 95.3% of seedlings and achieving a working speed of 1047.8 plants per hour. The authors emphasize that working speed is closely related to operational reliability. Excessively fast gripping, rotation, or transport movements may cause seedling damage or dropping. In the future, it is necessary to optimise motion coordination between the different units. Liu et al. (2019) predict that the developed system has the potential to replace manual labour in strawberry transplanting within elevated cultivation systems.

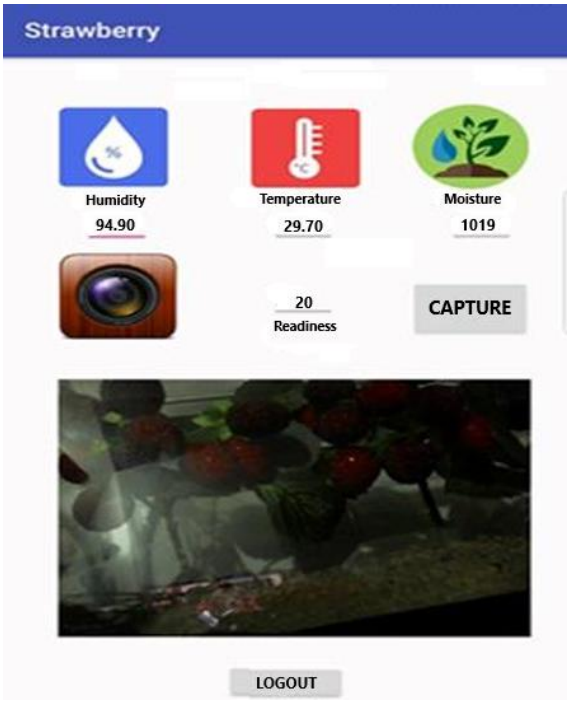
Figure 2
3D model of strawberry seedling transplanter

Source: (Liu et al., 2019).

Data on similar studies involving comparable crops can also be found in research databases. Khadatkar (2023) developed a robotic transplanter equipped with an XY manipulator and a servomotor-driven jaw-type gripper. In tests conducted with 30-day-old chili plug seedlings, the transplanter achieved a 90.3% rate of successfully transplanted seedlings. Magar et al. (2025) developed and tested a seedling extraction mechanism that uses needle-type grippers and applies a closed-loop indexing system. The experiments demonstrated a 96.05% successful extraction rate without damaging the root ball. The device achieved a working speed of 34–38 extracted seedlings per minute. Cabbage and tomato plug seedlings were used in the tests.

Irrigation systems

Strawberry irrigation plays an important role in maintaining plant health and achieving stable yields. Because strawberries have a shallow root system, they respond quickly to changes in soil moisture. Over-irrigation may cause nutrients to leach from the soil and results in unnecessary water use, while insufficient watering can reduce fruit quality and overall productivity. The use of soil moisture sensors, evapotranspiration estimates, and local weather data helps growers better understand soil conditions and decide when irrigation is actually needed. By applying these technologies, it is possible to manage water more efficiently without compromising strawberry yield.



In the context of irrigation control systems, Vega Caicedo & Barco Jiménez (2018) developed a system aimed at maintaining soil moisture within an optimal range while also focusing on water and energy consumption. The control system was based on a Constrained Matricial Model Predictive Control (CMMPC) approach and a dynamic soil water balance equation, in which moisture changes depend on irrigation dose and evapotranspiration. Input data were collected over a three-year period. Compared with a Proportional–Integral–Derivative (PID) controller, the CMMPC reduced control signal energy consumption by approximately 33% under sunny and cold scenarios. In the rainy scenario, the energy reduction reached approximately 95%. Water savings achieved with the developed system were 2.07–2.30 L/h under typical conditions and 35.67 L/h in the rainy scenario. St Fort et al. (2025) conducted a study on the use of micro-irrigation systems as an alternative to traditional high-volume impact sprinklers in strawberry production in Florida. The research was carried out on a commercial farm. A micro-irrigation system such as Mini Revolver reduced water use by approximately 58% during the transplant establishment period and by 63% during freeze protection. Importantly, no significant differences were observed in transplant survival or yield compared to traditional irrigation systems.

In the sensor-based control study, Guéry et al. (2018) analysed an automated soil moisture management strategy on a commercial strawberry farm in Spain. The existing pulse irrigation method was compared with a sensor-based control system, where irrigation decisions were made based on soil volumetric water content measurements. The objective was to maintain soil moisture within an optimal range and reduce unnecessary water use. The sensor-controlled system reduced seasonal water consumption by approximately 21%, while no significant differences in total yield were observed between the two irrigation systems.

A similar study using soil moisture measurements was carried out by Belayneh & Lea-Cox, (2017) on a commercial strawberry farm in Maryland, USA. In this case, a wireless sensor network was set up with sensors placed at different soil depths so irrigation could be adjusted according to actual moisture levels in the field. The sensor-based approach was compared with the farm's usual irrigation practice, which followed a fixed schedule based mainly on experience. Depending on the field and season, water use was reduced by 17–29% when the sensor system was applied. At the same time, there were no noticeable differences in plant condition or total yield compared to the traditional method.

A more comprehensive solution was developed by Leonen & Teleron, (2022). An automated open-field irrigation system for strawberries was created. It included soil moisture sensors, air humidity and temperature measurements, a microcontroller, and automated valve control. The data were transmitted to the controller and were accessible to the user. In Figure 3, it can be seen how the user can monitor field measurements through the Android application. Irrigation was activated automatically when the soil moisture dropped below the predefined minimum threshold. Under real field conditions, the system prototype achieved 58.8% water savings compared to the grower's previous irrigation schedule, and no negative effect on root zone moisture maintenance was observed.

Crop monitoring

Strawberry monitoring is essential for detecting and evaluating plant health in a timely manner, as well as identifying diseases. Manual inspection is a time-consuming and subjective process. Automated solutions that use computer vision, sensors, image processing, and deep learning algorithms enable continuous monitoring of plant health, early disease detection, and a reduction in labour intensity.

In the context of monitoring data processing, Khan et al. (2026) conducted research on early disease diagnosis. A Strawberry Leaf Disease Inspection (SLDI) system was developed based on a YOLO-NAS deep learning model and demonstrated early disease detection during testing. A manipulator moved a RealSense camera between strawberry plants in a controlled greenhouse simulation environment, and the model detected diseases with 91.1% precision.

Li et al. (2025) conducted research with the aim of improving image processing quality by using the enhanced CAFM-Enhanced YOLOv8 detection model, which was designed to perform better under complex conditions such as occlusions, plant damage, and noisy backgrounds. The YOLOv8 model was optimised by adding an additional ultra-small detection head for capturing very small lesions and by introducing the Convolution and Attention Fusion Module (CAFM), which helps the model focus on relevant features. In addition, a PyQt5-based interactive real-time visualization system was developed. These improvements increased the mAP@50 (mean detection accuracy at a 50% overlap threshold) from 94% to 96%.

With the aim of developing a practical and economically accessible solution, Khosro-anjom et al. (2015) developed a low-cost real-time strawberry leaf disease diagnosis system. The device consists of an RGB camera, an embedded computing platform, a convolutional neural network, and software modules for image preprocessing and result output. The system was mounted on a simple push-type wheeled platform and moved through strawberry fields under outdoor conditions. Images were captured and analysed, achieving disease classification accuracy of over 90%.

An integrated monitoring and control platform was developed by Mirbod & Pritts, (2025).

Figure 4
Monitoring platform in field test

Source: Mirbod & Pritts, 2025.

The aim of the solution was to provide continuous monitoring of microclimate conditions and plant status

while reducing the need for constant human supervision. The system integrated air temperature, relative humidity, and soil moisture sensors, data acquisition nodes, and wireless transmission to a central platform. The platform was tested under real field conditions beneath a low tunnel cover, moving along a cable-based system, and ensured stable data collection throughout the testing period. Figure 4 shows the platform test under field conditions. The device was powered through a cable-based power supply system. The authors indicate that the platform has potential for further development through the integration of additional sensors and monitoring devices.

Mulching

Mulching is a process that can be used in strawberry plant management. It helps control soil moisture and temperature, as well as limit weed growth. In practice, both organic mulch made from plant residues and synthetic materials, such as plastic film, can be used. Nowadays, mulching is largely mechanized—various implements have been developed that are pulled by a tractor and ensure the application of mulch. Sensor-based systems are also being developed to help control the amount of material applied and improve the quality of work.

In their study, Amin et al. (2022) developed a tractor-drawn plastic mulch laying machine. The objective was to design and test equipment that would reduce the amount of manual labour required for mulching under field conditions. The machine includes bed forming units, a mulch film feeding mechanism, and soil pressing discs. During the development stage, attention was given to ensuring continuous operation and reducing the risk of film damage. The machine was tested in field conditions, and operating parameters such as forward speed, bed width, and hole spacing were adjusted and optimised. According to the reported results, compared with manual mulching, the developed machine reduced labour input by 97% and operational costs by 75%.

Chaudhari et al. (2024) developed an IoT-based crop residue mulching machine, intended for the mechanical application of organic mulch. The aim of the research was to create a system that would reduce manual labour requirements while ensuring controlled and uniform mulch distribution. The authors designed a tractor-driven crop residue shredding and spreading mechanism with Internet of Things (IoT) integration, including sensors (a load cell, a soil moisture sensor, and proximity sensors) for data transmission and real-time process monitoring. In Figure 5, the developed model of the device is shown. The performance of the system was evaluated through comparative analysis with manual mulching in terms of labour requirement, cost, efficiency, and mulch uniformity. Compared to manual mulching, the mechanized system reduces labour requirements by 70–90% and operating costs by approximately 70%.

Figure 5

Mulching machine

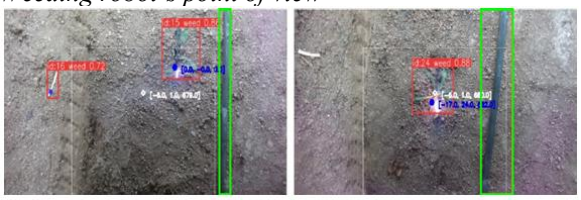
Weed control



Weeding in crop production is labour-intensive and is mostly done by manual work, and it is an important part of plant protection. In strawberries, weeding is more difficult because the plants are low, the planting is dense, and the foliage is thick. With the development of precision agriculture and robotics, computer vision and deep learning technologies are being used to separate weeds from crops in real time. Robots with laser or spraying systems are being developed and have the potential to reduce human involvement in weeding processes.

With the aim of developing a system capable of distinguishing weeds from crops in real time and performing targeted herbicide spraying, Liu et al. (2021) developed a mobile sprayer prototype equipped with cameras, solenoid valves, and microprocessor-based control. Three convolutional neural network models—AlexNet, GoogleNet, and VGG-16—were used for system control and weed classification. Experiments were conducted both under laboratory conditions and in the field. The highest weed recognition performance was achieved using the VGG-16 model. In field tests, the percentage of completely sprayed weeds reached 93%. It should be noted that the system performance decreased when the platform travel speed exceeded 3 $km \cdot h^{-1}$. The study indicates that the system has the potential to reduce herbicide usage in the weeding process and is suitable for weed control in strawberry cultivation.

Zhao et al. (2025) developed an autonomous laser weeding robot for strawberry fields based on the DIN-LW-YOLO vision model. The purpose of the study was to design a system that can detect strawberry plants, weeds, drip irrigation pipes and weed growth points in real time, and then direct a laser beam precisely to the weed. A mobile robot with an adjustable crawler chassis, a camera-based detection system and a laser unit was built. The control system relies on a deep learning model for navigation and target positioning. The experiments included building

a dataset from both greenhouse and open-field conditions under different lighting and growth stages. In total, 2,153 images were used for training and validation. The model achieved a mean average precision of 88.5% for region detection and 85.0% for growth point detection. In field tests, the weed control rate reached 92.6%, while the crop injury rate was 1.2%. The results indicate that the developed system can be applied for autonomous weed control in strawberry production. In Figure 6, laser weeding from the robot's point of view is shown.

Figure 6
Weeding robot's point of view

Truss pruning

Pruning is a regular maintenance task in strawberry cultivation and involves the removal of runners, excess leaves, and flower trusses. The automation of this process is hindered by the structural characteristics of the plant, which include dense foliage, limited visibility, and the requirement for precise mechanical cutting techniques. The automation of this process is facilitated by the integration of computer vision, deep learning segmentation models, RGB/RGB-D sensors, and precise manipulators.

The aim of the study by Fujinaga (2024) was to develop a multifunctional agricultural robot capable of performing both strawberry harvesting and truss pruning in a small-scale greenhouse. The researchers developed a system consisting of a crawler-type mobile platform, a 6-degree-of-freedom manipulator, a scissor-type cutting and gripping mechanism, and an RGB-D camera. Deep learning-based semantic segmentation (DeepLabV3+) was used to detect the cutting points. Pruning experiments were carried out in a greenhouse under semi-automatic operation. Out of 10 targeted trusses, 8 were successfully cut, resulting in an 80% success rate. The average pruning time was 23 s per truss. The results show that the system is able to perform pruning under real greenhouse conditions, although the success rate is influenced by gripping accuracy and the surrounding plant structure.

Vargas et al. (2025) developed a mobile robot system for strawberry pruning in polytunnel conditions. The system consists of the Thorvald mobile platform, two modified 5-degree-of-freedom manipulators, and several sensors, including RGB and RGB-D cameras, an IMU, and proximity sensors. A simulation environment with virtual strawberry plant models was also created to test perception and motion planning before real experiments. The paper mainly describes the system setup and experimental configuration. It does not report specific pruning success rates or operation times. The results show that the platform and simulation tools can support the development of autonomous pruning, but the system is still under further improvement. Figure 7 shows a visualization of the prototype under greenhouse conditions.

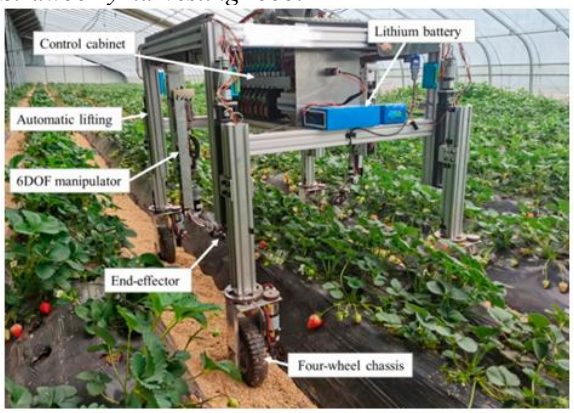
Berry harvesting

Strawberry harvesting is a labour-intensive task that has traditionally been performed by humans. Fruits must be harvested selectively according to their ripeness and handled carefully to avoid damage. Strawberries are sensitive to compression, and the harvesting process must be carried out precisely by cutting or picking at the stem, avoiding direct contact with the fruit itself. Computer vision, deep learning methods, and carefully designed manipulation systems make it possible to develop specialized strawberry harvesting robots. These robots are equipped with visual perception systems, multi-degree-of-freedom manipulators, and end-effectors.



With the aim of developing a cost-effective solution for open-field strawberry harvesting, Ochoa & Mo (2025) developed a pneumatically driven end-effector mounted on a Delta X parallel robot. The study focused on improving the design, so that the stem could be gripped and cut accurately without damaging the fruit or nearby leaves. The end-effector was manufactured using 3D printing. The mechanism combines a pneumatic cutter and a single gripping finger, allowing the stem to be held and cut at the same time. The system was evaluated through simulation and field tests at Farias Farms. In simulation, a harvesting success rate of 94.74% was achieved at a 90° rotation configuration. During field tests, the optimised setup reached a 100% success rate (32 out of 32 fruits). When operating at 0.7 m/s with an acceleration of 8 m/s², the average harvesting time was 2.80 ± 0.08 s, while at 4 m/s² it was 3.78 ± 0.08 s. These results show that the developed end-effector is capable of harvesting strawberries quickly and without visible damage under open-field conditions.

Chang (2024) developed a cable-driven, multi-joint robotic arm intended for use in a hydroponic greenhouse for the purpose of harvesting strawberries.

The system incorporates a cutting and gripping mechanism that cuts the stem and holds the fruit, thereby reducing direct pressure on the berry. A deep learning model has been integrated into the vision system to detect the position of strawberries in real time, determine the optimal picking point and estimate the contour of the fruit while the platform is in motion. Field trials were conducted within a greenhouse environment to assess fruit detection performance, harvesting success, and the time required to pick each fruit. The detection accuracy was 90%, while 82% of the harvesting attempts were successful. The mean duration of one strawberry selection was found to be 6.5 seconds, which decreased to 5 seconds when the arm return movement was excluded from the calculation.

Yu et al. (2024) developed a strawberry harvesting robot that can work in an unstructured greenhouse environment. The robot is intended for ridge-planting systems and operates with a double-arm cooperative mechanism. It includes two self-developed manipulators, a non-destructive stem-cutting end-effector, a lightweight Mask R-CNN-based vision system, and a CAN bus control system. The robot can detect ripe strawberries, determine the picking point, and coordinate both arms while moving along the ridge layout.

Figure 8
Strawberry harvesting robot

Source: Yu et al., 2024.

During field tests in a greenhouse under ridge-planting conditions, the harvesting success rate reached 49.30% in trimmed conditions and 30.23% in untrimmed conditions. In harvesting time tests, one arm required 7 seconds per fruit, while two-arm cooperation reduced this to 4 seconds per fruit. The robot performed navigation, fruit detection, stem cutting, and handling without human assistance. These results indicate that the system operates with a high degree of autonomy in real greenhouse conditions. The robot structure is shown in Figure 8.

The reviewed strawberry cultivation processes differ in their suitability for robotisation. Some operations are more structured and consist of repeatable mechanical actions. Transplanting is one of these processes, as it mainly includes seedling extraction from trays, transfer and placement in the soil. Irrigation management can also be automated relatively easily through the use of soil moisture sensors, weather data and automated control systems.

Monitoring and weed control have developed rapidly due to the use of computer vision and image processing technologies. These systems allow the detection of plant conditions, diseases and weeds in field conditions and support more precise crop management.

Other processes are more difficult to automate. Pruning and harvesting require precise interaction with the plant and careful handling of the fruit. Dense foliage and variable fruit position make these tasks technically more challenging. These processes still require further development of perception systems, robotic manipulators, and specialized end-effectors.

Several technologies already show practical performance in strawberry cultivation. In irrigation management, sensor-based control systems allow water supply to be adjusted according to soil moisture and environmental conditions. Field studies report water savings of around 17–29% with soil moisture sensors, while other automated control approaches show even larger reductions in water consumption without affecting yield.

Progress can also be observed in monitoring and weed control technologies. Image-based systems using deep learning models are able to detect plant diseases or weed presence with relatively high accuracy, which allows more targeted field management. In weed management applications, experimental robotic systems using vision models and laser or precision spraying technologies have demonstrated weed control rates above 90% in field tests.

Some progress is also visible in harvesting technologies. Recent robotic end-effector designs combined with machine vision systems are able to detect fruits and perform stem cutting with high success rates in experimental trials. Although these systems are still being improved for reliable operation in open-field conditions, the results indicate that automated harvesting is becoming technically feasible.

An important aspect in evaluating these technologies is their validation under real cultivation conditions. Compared with controlled greenhouse environments, open-field conditions introduce greater variability in lighting, plant structure and weather conditions. In the analysed studies, experimental robotic systems or prototypes were identified for most of the major cultivation processes, including transplanting, irrigation management, monitoring, weed control and harvesting. However, the reported tests were carried out under different conditions, including greenhouse systems, protected cultivation and open-field environments. Mulching represents a slightly different case. Although studies specifically reporting robotic systems tested in strawberry fields were not identified, similar mechanized technologies are widely used in

other horticultural crops. As the mulching process itself does not differ significantly between crops, these technologies can also be considered applicable to strawberry cultivation.

These results indicate that many of the key operations in strawberry cultivation are already technically feasible for automation at the prototype level. However, most of the developed systems are still in the experimental stage and require further improvement in reliability, operational speed and system integration before wider practical adoption. At the same time, a number of studies focus on individual technological components, such as perception systems, gripping mechanisms or navigation solutions, which demonstrate promising results but are not yet integrated into complete robotic platforms. Further development will therefore require the integration of these individual solutions into more comprehensive systems capable of performing multiple operations under practical field conditions.

In addition to the technological operations analysed in this study, a number of other processes are involved in strawberry plantation management that must be applied during certain periods in order to ensure proper maintenance of strawberry plantations. Such processes include field preparation prior to planting, mowing between rows if such a cultivation technology is applied, mowing and removal of strawberry foliage, removal of plastic mulch material after the end of production of perennial plantations, and other processes. In most cases, the implementation of these operations is technologically simple, and traditional solutions for performing them already exist in strawberry cultivation. However, from a future perspective, there is potential to improve these processes, which have so far been performed manually, and transfer them to automated or even fully autonomous robotic operation. This justifies the need for the development and improvement of equipment and technologies used in strawberry plantation management.

Conclusions

1. All analysed strawberry cultivation processes show high automation potential, and several robotic prototypes already demonstrate technical feasibility.
2. Many studies focus on individual technological solutions; further work should integrate these components into complete robotic systems.
3. Machine vision, sensors and intelligent control are key technologies for automating more complex strawberry cultivation processes.
4. Further research should improve system intelligence and adapt robotic technologies for reliable operation in open-field conditions.

Abstract
Diversification of energy flows is the main objective of the European Union's energy and climate policy. It is aimed at enhancing security of supply, reducing greenhouse gas emissions, and increasing system resilience. Despite common targets, EU member states demonstrate markedly different pathways and solutions in energy diversification. Often those strategies reflect constraints related to resource availability, legacy infrastructure, energy policy design, and socio–economic conditions. This study analyzes how select European Union member states are transitioning their energy sectors to align with overarching EU targets. It then considers the implications for Latvia's energy system. Using a comparative review methodology, the research evaluates national practices across electricity generation, heating, and combined heat and power production. Specifically, it assesses how these energy strategies align with local natural resource availability, energy import dependencies, and the technologal efficiencies of energy conversion. Latvia represents a distinct case study due to its high reliance on biomass, extensive district heating infrastructure, and limited domestic fossil fuel reserves. These structural conditions present both opportunities and challenges for Latvia's energy transition. By conducting a comparative analysis of EU member states practices, this study seeks to explain variations in energy transition progress and pinpoint the principal structural barriers facing Latvia's policy implementation. Ultimately, the study's findings will provide foundation for future research on energy system optimization, emphasizing the need to account for country-specific constraints and structural limitations.
Keywords: energy source, renewable energy, energy supply sustainability.

Introduction

The European Union has been working hard to change its energy policy. It wants to use more renewable energy, be more energy efficient, and get its energy from different sources. This is especially true after the EU adopted some big plans like the Energy Union Strategy, the European Green Deal, and the REPowerEU plan. These plans aim to reduce the EU's reliance on fossil fuels from other countries, make more renewable energy at home, and be better prepared for problems that might come from other countries or the market (Ah-Voun et al., 2024; European Comission, 2022).

Stable policies, support programs, investor trust, administrative processes, grid access, and sustained government commitment are all crucial for the targets set. Stronger and more consistent growth in renewable energy was demonstrated by nations like Germany that had robust and predictable support systems. On the other hand, nations with abrupt policy shifts, retroactive subsidy reductions, or difficult approval processes saw stagnation or decline (Shivakumar et al., 2019).

This review examines the mechanisms employed by selected EU countries to diversify energy flows and evaluates their alignment with EU strategic objectives. Some countries rely heavily on expanding variable energy sources such as wind and solar, while others prioritize the development of biomass – based energy systems, nuclear power, or energy efficiency improvements within existing infrastructure. Consequently, the effectiveness and pace of diversification differ substantially between member states. Comparative perspective is particularly important because EU member states exhibit representative but highly differentiated energy transition pathways shaped by their national circumstances.

Understanding how structural conditions influence diversification strategies is particularly important for countries with constrained resource bases or historically embedded energy infrastructures. Latvia represents a notable example within the EU energy landscape. The country is characterized by a relatively high share of renewable energy, largely driven by biomass and hydropower, as well as an extensive district heating sector that plays a central role in heat supply. At the same time, Latvia faces structural limitations related to limited domestic fossil fuel resources, a relatively small energy market, and historical dependence on imported energy carriers.

Given the differences across the EU, comparative analysis of national experiences can provide valuable insights into the mechanisms that enable or hinder diversification. Looking at how different countries in the EU deal with the challenges they face, use the resources they have, and match their plans with the EU's goals can help find common patterns that can be useful for countries with similar characteristics. By understanding how the availability of resources, technological development, and policy tools are connected, we can create strategies that are tailored to the specific needs of each country, which can help them diversify and grow in a way that makes sense for their unique situation.

Using a comparative qualitative review of literature and energy system analyses, the study examines the diversification strategies of several EU countries representing different energy system structures. The findings are then discussed in relation to the Latvian energy system to identify key structural constraints and opportunities relevant to further diversification of

energy flows. The findings provide a foundation for further analytical, engineering, and environmental studies focused on optimizing energy systems under national constraints.

Materials and Methods

In this study, diversification of energy flows is understood as the expansion and balancing of multiple energy sources, supply pathways, and conversion technologies within an energy system. The aim of this process is to reduce dependence on a limited number of fuels or suppliers and to improve system resilience. Diversification may occur across several dimensions of the energy system. First, diversification of primary energy sources involves increasing the variety of fuels and renewable resources used in electricity and heat generation (biomass, wind, solar, hydropower, nuclear energy, and fossil fuels with different supply origins). Second, diversification can occur through supply structures, including the balance between domestic energy production and imported energy carriers, as well as the use of alternative supply routes. Third, diversification may involve conversion and generation pathways, including different technological solutions such as combined heat and power (CHP), district heating systems, decentralized generation, and renewable–based electricity production. Finally, diversification can be associated with increased system flexibility, including energy storage, sector coupling, and the integration of variable renewable energy sources.

In this article, diversification is therefore examined as a multidimensional characteristic of national energy systems, reflecting both resource availability and structural conditions that influence the range of feasible technological and policy pathways. The review covers studies from the past decade - a period when EU energy policy focused on cutting carbon emissions, enhancing energy security, and strengthening grid resilience. To ensure a consistent analysis, we need to evaluate how different countries are diversifying their energy sources. The dimensional comparison framework is presented in Table 1.

Table 1

Dimensions and indicators used to evaluate energy flow diversification

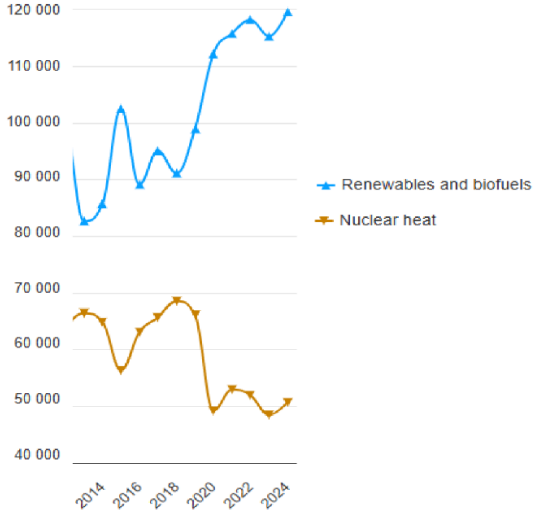
Dimension of diversification	Indicators examined
Energy sources	Share of renewables, fossil fuels, nuclear
Supply structure	Import dependence, domestic production
Conversion technologies	CHP, district heating, renewable generation
System flexibility	Storage, sector coupling

The framework examines multiple dimensions of the energy system, including primary energy sources, supply chains, energy conversion efficiency, and system flexibility. This enables an equitable comparative analysis, taking into account national differences in resource endowments, infrastructure, and regulatory policy. Applying this framework provides deeper insight into national energy diversification strategies and highlights optimal approaches across diverse contexts.

Six national energy systems are considered in the analysis. Latvia is examined as the central case study, while five additional EU member states are selected to represent contrasting structural characteristics within the European energy landscape. The selected countries illustrate different combinations of resource endowments, technological pathways, and historical energy system development. In particular, the analysis includes countries with strong biomass – based energy systems, high penetration of variable renewable energy sources, nuclear–dominated electricity generation, and fossil fuel–dependent energy structures. By comparing energy system configurations, this study aims to identify emerging patterns in how European Union member states pursue energy diversification, given their respective structural constraints. The insights derived from this comparative review provide a basis for evaluating the opportunities and limitations associated with further diversification of energy flows in Latvia.

Results and Discussion

Sweden



Sweden represents one of the most advanced examples of energy system, characterized by a long– standing transition toward low–carbon energy sources and strong government support for expanding renewables. The Swedish electricity system is largely based on hydropower and nuclear energy, which together provide stable low–carbon baseload generation, complemented by increasing shares of wind power and biomass. In recent years, political discussions have renewed interest in expanding nuclear capacity as part of efforts to meet rising electricity demand associated with electrification and industrial transformation (Morgunova & Linné, 2026).

Another distinctive feature of the Swedish energy system is the extensive use of district heating, which supplies a large share of the national heat demand. Moreover, it enables the integration of multiple energy sources and technologies. District heating systems facilitate sector coupling between electricity and heat sectors through technologies such as CHP plants, heat pumps, and thermal energy storage, thereby improving system flexibility and enabling higher shares of renewable energy (Atabaki et al., 2026).

Swedish citizens generally favor a balanced approach, regarding neither total centralization nor complete decentralization as ideal. Sweden’s experience demonstrates that the best approach combines the two:

the national government should establish goals, provide financing, laws, and oversight, while local governments should modify and carry out policies in accordance with local circumstances (Maliszewska-Nienartowicz & Stefański, 2024).
Figure 1 illustrates the Swedish electricity generation mix from 2014 to 2024.

Figure 1
Gross electricity production in Sweden, GWh (Eurostat, n.d.)

Swedish electricity production is almost entirely fossil–free, with around 96 – 99 % of electricity from renewable or nuclear sources. As of 2025, statistics highlight the dominant sources in Sweden's electricity mix:

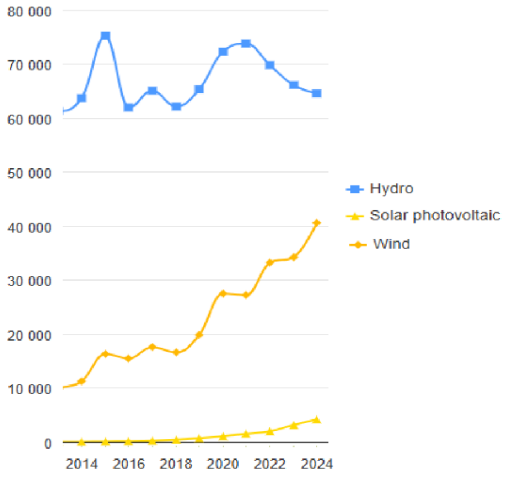
- Hydropower: ~39 %
- Nuclear: ~28 %
- Wind: ~23 %
- Biofuels and waste: ~8 %
- Solar: ~2 %

The last decade's trend shows a rapid expansion of renewables as well as a slow decrease in nuclear power. This rapid increase in renewable energy production is mainly connected to increasing wind energy capacities rising from 11235 GWh to 40621 GWh in the depicted time period. Solar generation increased sharply from 47 to 4163 GWh, yet its total volume remains modest in comparison to wind energy. Electricity production from renewables is shown in Figure 2.
However, some perspectives emphasize that maintaining nuclear operations is essential for Sweden to meet rising demand, sustain RES, and preserve grid stability.

Denmark

Denmark is one of the most advanced examples of renewable–based system in the EU with strong policy support for wind energy development. Denmark has pursued a long–term transition away from fossil fuels through a combination of regulatory measures and financial incentives aimed at increasing the share of renewable energy in both electricity and heat production. Early policy frameworks supporting renewable electricity generation, particularly wind energy, created favourable market conditions that allowed Denmark to develop significant technological and industrial leadership in wind power deployment.
Wind energy now plays a central role in the Danish electricity system, supported by extensive onshore and offshore wind capacity in the North Sea. Offshore wind development is expected to continue expanding in the coming decades, supporting both national decarbonization goals and regional electricity supply within the interconnected European energy system (Abid et al., 2026).

Figure 2
Gross electricity production from renewables in Sweden, GWh (Eurostat, n.d.)



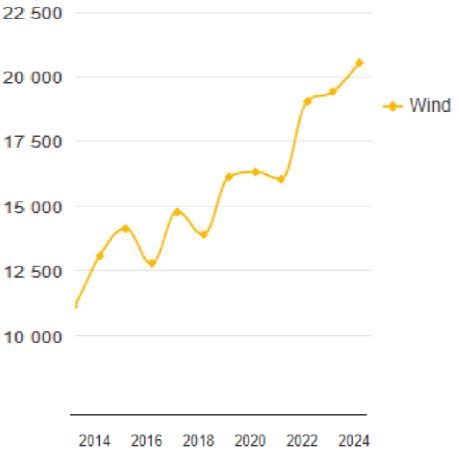


Figure 3 depicts the growth of wind energy capacities in Denmark for the period from 2014 to 2024. In this relatively short timeframe, wind energy production rose form 13000 GWh to 20500 GWh. Wind remains the largest electricity source providing almost 60 % of the whole country's production.

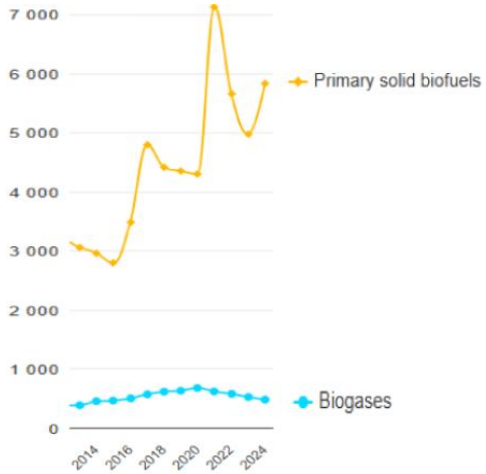
Figure 3
Wind electricity production in Denmark, GWh (Eurostat, n.d.)



Biomass is the second source of electricity providing almost 20 % of state production capacities. Danish CHP plants supply both electricity and district heating facilitating sector coupling between electricity and heating sectors, allowing surplus renewable electricity and industrial waste heat to be integrated into the heating network. CHP plans improve energy conversion efficiency and system flexibility, supporting the management of variable renewable energy generation (Ono et al., 2026).

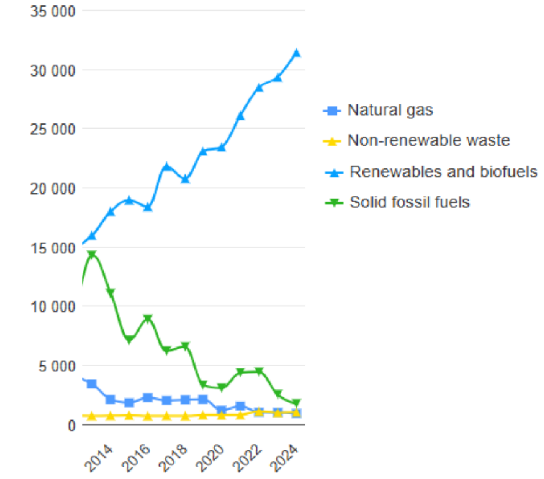
Solid biofuel and biogas use in electricity production is shown in Figure 4. In the same timeframe, solid biofuel consumption expanded from 2959 to 5837 GWh; in contrast, biogas consumption experienced minimal growth, moving from 451 to 478 GWh.

Figure 4

Combustible renewables in electricity production in Denmark, GWh (Eurostat, n.d.)

By increasing wind and biofuel capacities, Denmark was able to cut off its solid fossil fuel use from 11064 GWh in 2014 to 1751 GWh in 2024. Natural gas consumption in electricity production also decreased from 2096 to 909 GWh in the depicted time frame. Denmark's electricity production trends are shown in Figure 5.

Denmark's energy transition is therefore often referred to as a 'smart energy system' approach of renewable electricity, district heating, as well as emerging innovations in hydrogen and synthetic fuels. These initiatives support both decarbonization and energy security objectives (Marczinkowski et al., 2022).

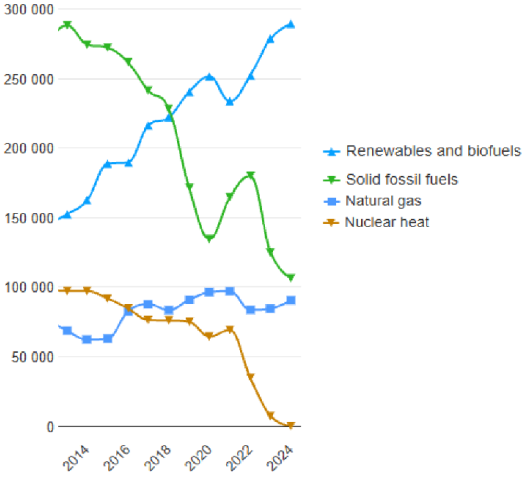


Germany

Germany represents one of the most ambitious energy transition initiatives through its *Energiewende* strategy, which aims to transform the national energy system by expanding renewable energy while phasing out nuclear and coal power.

The German electricity mix has increasingly shifted toward wind and solar generation (Figure 6), supported by strong policy mechanisms such as feed – in tariffs and market incentives for renewable energy investment.

Figure 5



Gross electricity production in Denmark, GWh (Eurostat, n.d.)

Market liberalization and regulatory reforms have also enabled the emergence of new actors and energy technologies within the electricity sector (Pant & Belz, 2026).

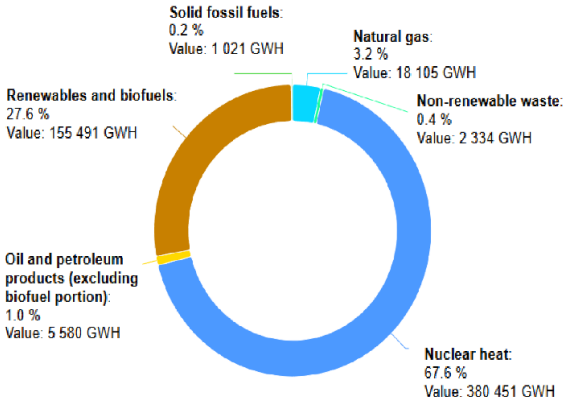
Figure 6

Gross electricity production in Germany, GWh (Eurostat, n.d.)

At the same time, Germany faces significant challenges associated with the integration of large shares of intermittent renewable energy. The rapid expansion of wind and solar capacity has led to periods of surplus generation while electricity demand remains concentrated in industrial regions, requiring major investments in grid infrastructure and transmission networks to ensure system stability and efficient electricity distribution. Incentive regulation mechanisms have been implemented to stimulate investment in grid expansion and modernization (Matschoss et al., 2019).

Another key component of Germany's energy transition is the gradual phase-out of coal-fired power plants, which historically played a central role in the country's electricity generation. As the world shifts

towards cleaner energy, climate policies and increasing fuel costs are likely to speed up the end of coal-powered generation. At the same time, renewable energy sources, gas-fired power plants, and new technologies like battery storage are stepping in to replace old fossil fuel capacity. This shift occurs within a broader transitional period and is expected to significantly alter the energy generation landscape. As coal is phased out, these alternative energy sources are becoming critical to meeting growing national demand. According to recent studies, coal is anticipated to lose its central role in electricity generation by 2030. But we will still need some traditional power plants that can adjust to changes in demand. Future reliance on these plants hinges on three main variables: overall electricity demand, the share of renewables in the power mix, and the relative prices of coal and natural gas (Egerer et al., 2025).

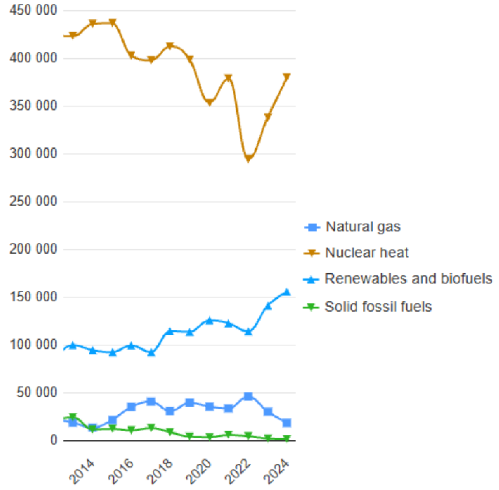


Despite the expansion of renewable energy sources, the German power system still faces economic and technological challenges, such as high electricity prices, infrastructure bottlenecks, and the rising need for critical materials needed for renewable technologies. Such factors indicate the difficulty of achieving large-scale energy diversification in highly industrialised economies. Germany thus exemplifies diversification by large scale renewable deployment, but under large infrastructural and economic constraints (Egerer et al., 2025).

France

France represents a structurally unique case due to its traditional reliance on nuclear power plants as the backbone of its electricity system. Nuclear power has historically produced around 70 % of all electricity generation (Figure 7), enabling France to maintain low greenhouse gas emissions and a comparatively high degree of energy independence. This centralized, large-scale generation model has been a defining feature of French energy policy since the 1970s and continues to shape its diversification pathways.

Figure 7



France, gross electricity production in 2024, GWh (Eurostat, n.d.)

In recent decades, however, France has gradually reoriented its energy policy toward alignment with European climate objectives, including increasing the share of renewable energy and reducing fossil fuel consumption. Recent geopolitical tensions and war in Ukraine also forced EU countries to cut their fossil fuel use; therefore, France was forced to increase its nuclear generation (Figure 8). Despite these ambitions, the transition has been non-linear, reflecting both institutional inertia and the complexity of modifying an already low-carbon, highly centralized system (Andriosopoulos & Silvestre, 2017).

Figure 8

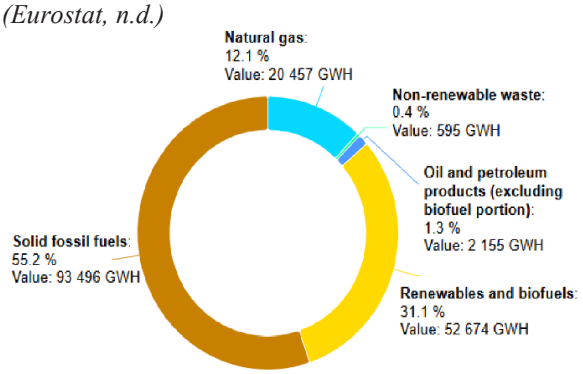
France, gross electricity production, GWH (Eurostat, n.d.)

A key structural challenge in the French case lies in balancing the reduction of nuclear dependency with the expansion of renewable energy sources. Policy targets aim to reduce the share of nuclear power to approximately 50% of electricity generation while simultaneously increasing the share of renewables to 32% of final energy consumption by 2030. However, achieving those targets requires significant investments in infrastructure and system flexibility (balancing and accumulating facilities), as well as careful management of supply security and electricity pricing (Andriosopoulos & Silvestre, 2017).

Furthermore, France's energy diversification strategy is constrained by institutional structures built around centralized generation and state-supported energy companies. While renewable energy technologies such as wind and solar are expanding, their integration into the existing system presents technical and economic challenges, particularly in terms of grid adaptation and market design. Thus, France demonstrates a diversification pathway constrained by nuclear generation dependency and centralized system architecture (Xuan, 2025).

Poland

Poland represents a structurally constrained case of energy diversification with strong dependence on coal and a relatively slow transition toward renewable energy. Despite increasing pressure from EU climate



policies, Polish energy system remains dominated by centralized, fossil-based generation (Figure 9).

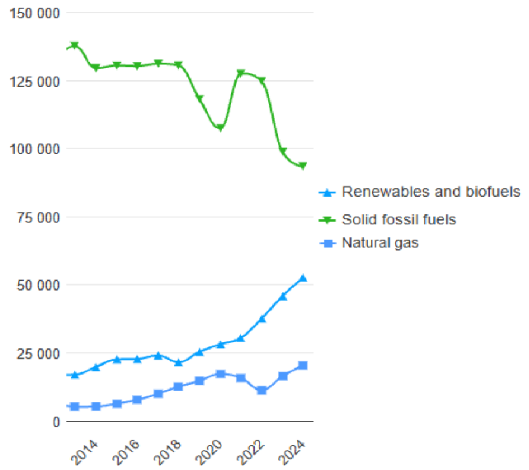
Recent developments, however, reveal a more complex transition dynamic. Poland has experienced a rapid expansion of distributed renewable energy, particularly in the form of residential photovoltaic installations. This 'prosumer-driven' process has increased public engagement and created a foundation for more decentralized generation models. Nevertheless, this transition remains fragmented and insufficiently integrated into the broader energy system (Xuan, 2025).

Another structural barrier to diversification in Poland is the gap between the lack of government involvement and practical implementation. EU directives promote mechanisms such as renewable energy communities (REC), but their deployment in Poland is still limited. The conditions are largely a combination of political conservatism, regulatory lag and insufficient institutional support, all of which act as a drag on investment (Neska et al., 2025).

Figure 9

Poland, gross electricity production in 2024, GWH (Eurostat, n.d.)

Moreover, the Polish energy system is limited by infrastructural and socio-economic limitations. The continued use of centralised energy management, limited system flexibility and ageing grid infrastructure complicate the integration of RES. Low levels of public trust, limited social capital and a preference for individual rather than collective energy solutions also hinder the development of large-scale renewable energy models (Neska et al., 2025).



These challenges notwithstanding, the rapid uptake of small-scale renewables signals an increased societal willingness to change. Renewable energy capacities rose from 19 842 to 52 674 GWh (Figure 10).

As such, Poland illustrates both difficulties and opportunities associated with energy transition, highlighting the importance of institutional involvement, regulatory stability, and social engagement in achieving diversification goals.

The European energy systems analysed show substantially different pathways of energy transformation. These are determined by various drivers such as resource availability, infrastructure development and policy priorities.

Figure 10

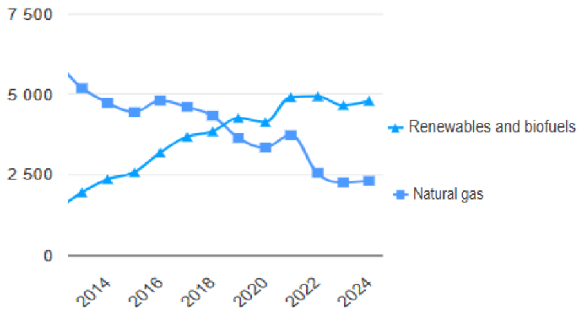
Poland, gross electricity production, GWH (Eurostat, n.d.)

The comparative analysis of selected European countries shows that energy diversification is not a uniform process but a set of sequential actions driven by resource availability, institutional frameworks and existing energy systems. All the analysed countries operate in a common EU policy framework, but their strategies for diversification differ to a greater or lesser extent, both with respect to strategy and effectiveness. Across all cases, structural constraints emerge as a decisive factor shaping diversification outcomes. These constraints include not only physical infrastructure and resource endowments, but also institutional involvement, market design, and societal factors. The transition dynamics are more complex in countries with higher levels of structural inertia or policy fragmentation (e.g. Poland and, to a lesser extent, Germany) compared to countries with stable policy environment and integrated system planning (e.g. Denmark and Sweden), where diversification is more effective.

From a broader perspective, the comparative analysis indicates that successful energy diversification requires not only technology deployment but also system level integration and institutional engagement. Ultimately, the success of diversification strategies depends on the interplay between the adoption of new energy sources, modernisation of infrastructure, policy frameworks, and societal factors.

These findings provide an important basis for the analysis of the Latvian energy system, which has a peculiar set of challenges and opportunities for energy diversification in the context of the EU.

Latvia



District heating and combined heat and power (CHP) systems are a defining feature of Latvia's energy sector. District heating, especially in urban areas, represents a significant share of the total energy consumption and is characterised by a high level of centralisation that originated from the historical development of the system. Combined heat and power

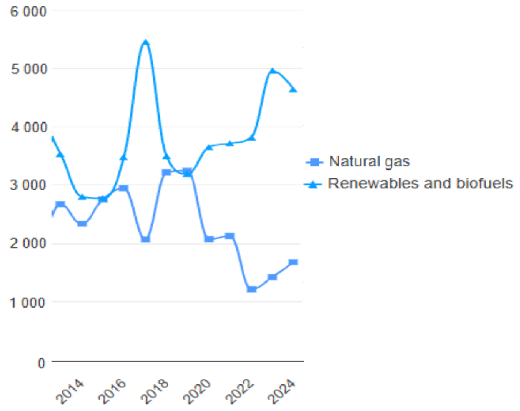
(CHP) generation is of vital importance, as CHP plants account for approximately 70% of the consumer heat supply. This structure creates both opportunities and constraints for diversification. CHP systems can convert energy very efficiently, but they also create dependence on certain types of fuel, especially natural gas.

The role of renewable energy is increasing, but the energy mix in Latvia is still influenced by natural gas in heat and electricity production. In district heating, natural gas accounts for a substantial share of heat production, with substantial share CHP-generated heat relying on gas. Meanwhile, biomass – primarily wood fuel – plays an increasingly prominent role in smaller boiler houses and decentralized systems, leveraging abundant domestic forestry resources. This dual structure positions Latvia between Sweden's biomass-driven system and Poland's fossil-dependent model. Heat energy produced from natural gas decreased from 4732 GWh in 2014 to 2311 GWH in 2024, renewable and biofuel heat capacities rose from 2365 to 4660 GWh (Figure 11) and are expected to grow even more because of upcoming waste incineration plant installation in Acone. This waste – to – energy CHP plant will strengthen Latvia's energy independence by lowering natural gas consumption.

Figure 11

Latvia, gross heat production, GWH (Eurostat, n.d.)

Another important structural characteristic is the high concentration of energy demand in urban centres, particularly Riga, which accounts for more than half of country population and total heat production. This spatial concentration limits the expansion potential of new district heating infrastructure in other regions and influences the feasibility of large-scale system transformations. At the same time, total heat demand has shown a declining trend in recent years due to efficiency, indicating evolving consumption patterns (Kamenders et al., 2017).

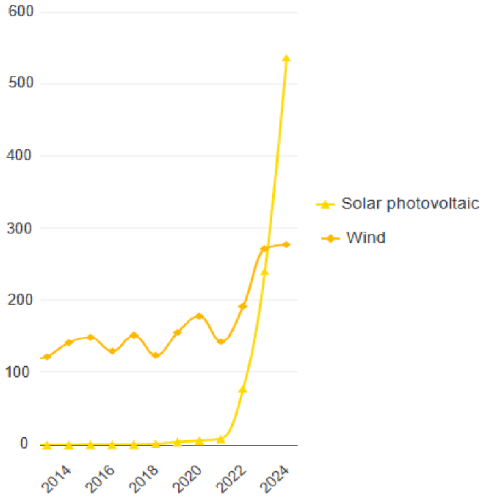


In terms of electricity production Latvia has lowered its natural gas consumption from 2337 GWh in 2014 to 1678 GWh in 2024 as shown in Figure 12.

Intermittency of the renewable energy capacity is referred to hydro power plant yearly output changes since hydro power has the largest share of Latvia's electricity production portfolio.

Hydropower plants remained the main source of electricity generation in Latvia in 2025, generating slightly more than half, or 51%, of the total amount of electricity transmitted to the network, but this figure is decreasing every year (Electricity market overview, 2025).

Figure 12



Latvia, gross electricity production, GWH (Eurostat, n.d.)

The primary reason for this shift is gradual increase in wind and solar power generation. In 2024, wind output reached 273 GWh while solar reached 398 GWh; in 2025, these figures shifted to 200 GWh and 678 GWh, respectively (Electricity market overview, 2025) (Figure 13).

Figure 13

Latvia, gross electricity generation from solar and wind resources, GWH (Eurostat, n.d.)

This dataset does not account for the capacity of the new Kauguri wind farm (16 modern turbines with a maximum tip height of 266,5m), which is expected to begin commercial operation this July and produce more than 350 GWh energy per year (Laflora Energy Wind Park, 2026).

This same indicator for biomass and biogas usage for electricity production would be accordingly 286 and 153 GWh in 2024, and 281 and 117 GWh in 2025 (Electricity market overview, 2025).

From a diversification perspective, Latvia demonstrates moderate progress, with decreasing consumption of natural gas, and gradual growth of renewable energy capacities. However, projections indicate that natural gas will remain part of the energy balance, reflecting structural and infrastructural inertia. This highlights a key challenge, also observed in other EU countries: the difficulty of fully transitioning away from established energy carriers within existing system configurations (Kamenders et al., 2017).

Importantly, the Latvian system presents many opportunities for diversification within existing infrastructure, particularly through the modernization of district heating and CHP systems. The widest potential for improving is through low-temperature district heating, heat storage integration, and advanced CHP technologies. These developments directly enable the integration of alternative fuels into biomass-based systems, including co-incineration strategies in fluidised bed technologies.

Latvia in the wider EU context could be described as a structurally adaptable but resource-constrained system. In this context, diversification is less a matter of large-scale capacity expansion, and more of optimisation of existing energy flows. Latvia's path is more infrastructure-driven and incremental, compared to Denmark's highly integrated renewable systems or Germany's large-scale renewable deployment.

Overall, the findings suggest that Latvia's most effective transformation strategy lies in enhancing system flexibility and fuel diversity. While expanding renewable capacity will reduce the country's reliance on natural gas, renewable deployment alone is insufficient. This is particularly evident in the heating sector, which consumes slightly more natural gas than power generation (2311 GWh compared to 1678 GWh in 2024). In this context, a promising pathway involves integrating alternative fuels into biomass cogeneration systems, complementing the construction of a waste-to-energy CHP plant that is already underway. These technologies will improve energy security, reduce fossil fuel dependence, and align with EU climate objectives. Latvia's diversification challenge is therefore not primarily the absence of renewable potential, but also the need to adapt existing heat and cogeneration infrastructure to a more flexible and less fossil-dependent fuel mix.

The general lesson from the Latvian case is that in smaller, infrastructure-limited energy systems, diversification is a slow process of building up system flexibility, renewable expansion and resilience under existing structural conditions.

Conclusions

1. The research indicates that energy diversification within the European Union is driven chiefly by resource endowment, institutional structures, and existing energy system configurations.
2. The comparative analysis identified distinct national approaches to diversification, confirming that successful energy transition strategies depend on system-specific conditions rather than a universal model.
3. Effective energy diversification requires not only the expansion of renewable capacity, but also infrastructure modernisation, market design reform and sector coupling.
4. Latvian energy system can be described as structurally adaptable but constrained by its reliance on natural gas, and limited expansion potential of conventional renewable resources.
5. For Latvia, the most promising path toward diversification lies not in the rapid expansion of renewable capacity, but in enhancing fuel flexibility, expanding CHP output, and modernizing existing district heating and CHP infrastructure.

IMPACT OF PRATT TRUSS MEMBER SIZING ON OPTIMAL SOLUTIONS

Arturs Neiburgs

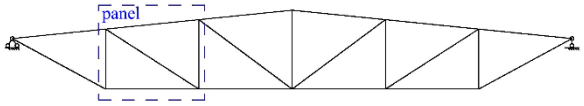
Corresponding author's email: arturs.neiburgs@gmail.com

Abstract
Buckling frequently governs the design of compression members, so optimization approaches that consider only material stress utilization can lead to solutions that are not practically optimal. Efficient designs depend not only on sizing but also on selecting a topology that promotes stable force transfer. This study provides an in-depth investigation of the behaviour of the Pratt truss topology for trusses with varying span, number of panels, and height. Pratt trusses were simulated and optimized (157,212 unique cases) using alternative member-sizing strategies. Results were evaluated using statistical and graphical analyses to compare sizing models. For the Pratt truss topology, consistent response patterns in internal force distribution, stiffness, and optimal height-to-span ratio are observed across the investigated design space, largely independent of the sizing approach. However, a max-utilization sizing rule for members produces substantial dispersion in the result data. Optimal solutions obtained using regression analysis exhibit linear relationships between trusses of different spans with the same number of panels. The optimal height-to-span ratio follows distinct trends for different panel counts. For a fixed panel count, it varies smoothly and correlates strongly with span. Overall, the results indicate a distinct type of behaviour inherent to the Pratt truss topology, suggesting that, when generalized, these trends can support faster pre-design evaluation of near-optimal truss configurations.
Keywords: pratt truss topology, minimum-weight design, iterative finite element analysis, genetic algorithm benchmarking, buckling constraints.

Introduction

Structural efficiency is governed not only by member sizing but also by the chosen load-transfer mechanism, which is primarily determined by shape and topology. Conceptual decisions therefore have a first-order influence on material demand and stiffness, and later sizing adjustments cannot fully compensate for an inefficient structural layout (Baker et al., 2015). For steel roof trusses, this challenge is amplified by the fact that compression design is frequently governed by stability, so the 'best' solution depends on buckling-sensitive member selection rather than on stress utilization alone (Neiburgs & Skadins, 2024). In addition, practical design introduces discrete cross-sections from catalogues, multiple verification rules, and serviceability constraints, all of which tend to make optimization problems computationally demanding and can push many studies toward simplifying assumptions that risk producing solutions requiring substantial post-processing by the engineer (Kripka & Drehmer, 2018). Heuristic global search methods such as genetic algorithms are therefore often used to explore large, discontinuous truss design spaces (including topology/configuration choices) when closed-form or gradient-based optimisation is impractical (Verbeeck et al., 2004). Because of these limitations, several researchers have emphasized the need for conceptual-stage approaches that relate structural performance to a small number of geometric descriptors. One well-established direction is the use of morphology-based indicators (De Wilde et al., 2015), which link slenderness measures such as L/H to volume (strength) and displacement (stiffness) trends and can incorporate buckling effects to guide early decisions (Pyl et al., 2013). At the same time, studies that explicitly include additional phenomena (e.g., buckling and stiffness constraints) demonstrate that fully stressed or 'max utilization' reasoning does not necessarily deliver the lightest structure (Vandenbergh et al., 2006). These observations motivate a more detailed investigation of how practical sizing rules interact with truss topology when discrete catalogues and stability checks are enforced.

Within this context, the present study focuses on the Pratt truss, a widely used topology in building roofs. The research aim is to quantify how alternative member-sizing strategies influence the predicted optimal solutions and the resulting trends in key geometric parameters, with emphasis on the optimal height-to-span ratio and its dependence on span and panel count. The approach is based on a large parametric dataset of simulated and optimized Pratt trusses, followed by statistical post-processing to identify systematic relationships and to distinguish genuine topology-driven trends from sizing-induced dispersion. The study also evaluates whether such trends can support faster pre-design estimation of near-optimal configurations, which is relevant in practice where weight is often directly tied to embodied impacts for single-material structural systems (Ching & Carstensen, 2022).



Materials and Methods

This study investigates the structural response of a Pratt truss supported at the top chord ends. The span varies from 12–25 m (1 m steps) and the height from 1.00–3.55 m (0.05 m steps). For all cases, the ridge is 0.5 m above the supports, producing different top-chord slopes while keeping comparable overall heights. The topology is defined by the panel count $n_p \in \{4,6,8,10,16,20\}$ for each span–height pair. One panel is the bay between two adjacent panel points along the span, as illustrated in Figure 1.

The calculations were performed in Rhino 8 using Grasshopper as the computational environment, where custom 2D planar finite element method (FEM) and member-sizing algorithms were developed for this study. A linear-elastic, pin-jointed FEM truss model is

used and self-weight is neglected, consistent with early-stage morphological-indicator comparisons of large candidate sets (French, 1985). One load pattern is applied at two levels (4 and 6 kN/m²) over a 6 m tributary width along the full span; the resulting line load is converted to equivalent nodal loads and applied to upper-chord nodes according to truss geometry. Two boundary-condition variants are analysed: pinned-simple and pinned-pinned. All members are initially assigned a uniform area of either 0.0043 m² or 0.01 m². Each case is solved using an iterative FEM-sizing loop (11 iterations): member forces drive profile updates that are reintroduced into the FEM model. Convergence is monitored via the relative change in total truss weight between iterations (ΔW/W); cases with nonzero last-step change are retained as part of the dispersion.

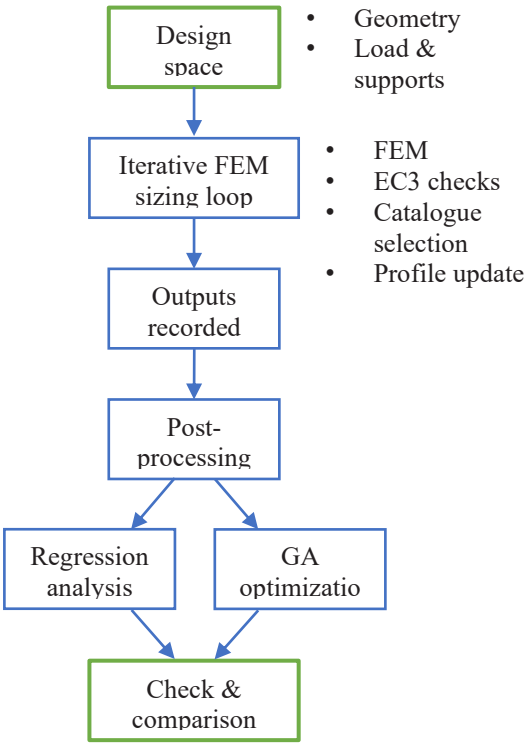


Figure 1
Pratt truss schema

A compact overview of the computational procedure is provided in Figure 2 (workflow schema), summarizing the parametric model, the iterative FEM-sizing loop, response recording, and post-processing. Truss member sizing is treated as the primary modelling variable. Member resistances are verified according to Eurocode 3 (European Committee for Standardization, 2022) for tension and compression prior to profile acceptance; compression stability is checked for pin-ended members with effective length factor k=1.0 (effective length equals the node-to-node length) using the Eurocode 3 (EC3) buckling reduction-factor method with buckling curve b (α=0.34) and utilization $U=N_{Ed}/N_{b,Rd}$; Class 4 profiles are excluded, hence gross section properties are used; nominal loads are used (no action factors) with $\gamma_{M0}=\gamma_{M1}=1.0$, and tension resistance is taken as gross yielding only (no net-section/fracture checks). Profiles are selected from a predefined catalogue using one of two selection rules: maximum utilization or minimum weight among feasible profiles. Here, 'feasible' refers only to member-level Eurocode 3 checks. Joint detailing and cross-section compatibility between connected members are not modelled. For each rule, four sizing approaches are investigated to quantify the influence of sizing assumptions on the resulting optimal solutions. In A1, no catalogue-based sizing is applied, and the initial cross-sections remain unchanged. In A2, profiles are selected from a mixed catalogue including I and U-sections and square/rectangular hollow sections. In A3, profiles are selected from a custom rectangular hollow section catalogue with monotonically increasing dimensions and wall thickness. In A4, the mixed catalogue of A2 is combined with a fabrication constraint: all upper-chord members share one profile, and all lower-chord members share one profile, taken as the largest required along each chord. This improves constructability and reduces variation in connected member sizes. All cases use steel grade S355.

The study includes N_{geom} = 4,367 valid configurations. With three sizing approaches (A2–A4), two sizing strategies, and six load/support cases, the total is: N_{cases} = 4367 · 3 · 2 · 6 = 157,212. A1 is evaluated once as a reference and is not included in N_{cases}.

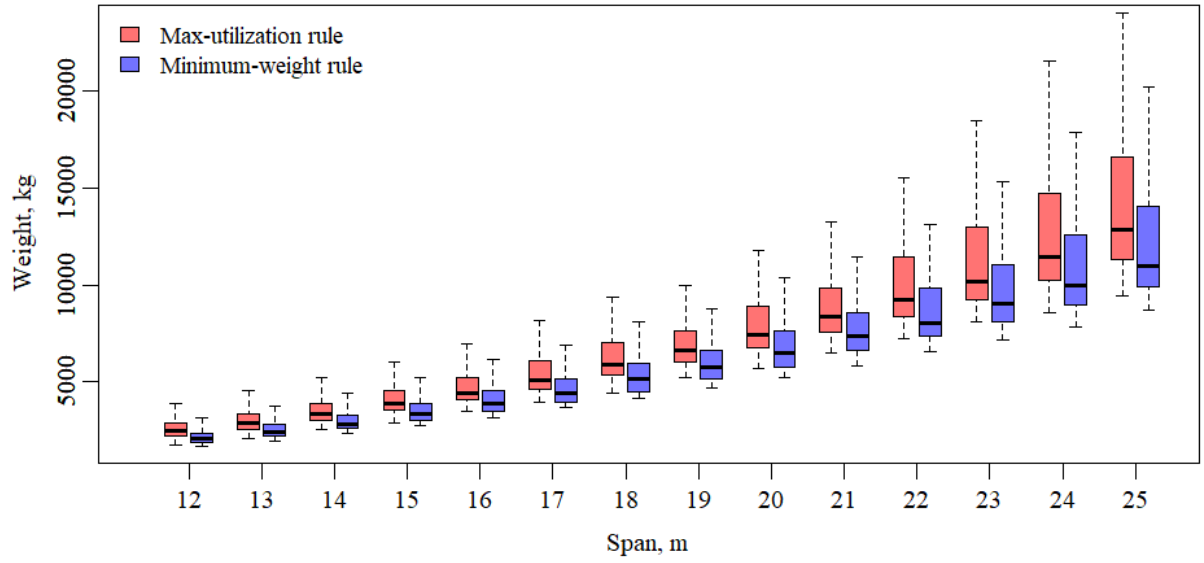
Figure 2
Iterative FEM-sizing and post-processing workflow

During the iterative procedure, the recorded outputs include geometric descriptors, support reactions, member force measures, selected profiles, total truss mass, and vertical deflections, stored for each iteration together with the corresponding modelling metadata.

The results are analysed using statistical methods and graphical interpretation. Data are grouped by profile selection rule, sizing approach, and support configuration, and subsequently evaluated with respect to panel count and span. To characterize the relationship between truss weight and height for fixed span and panel count, a quadratic regression model of the form Tweight=a+b·Theight+c·Theight² was fitted in R using ordinary least squares, implemented as lm(Tweight ~ poly (Theight, 2, raw = TRUE)). Separate models were fitted for each span–panel subset within each analysed dataset, giving 84 quadratic models in total. Each regression used 52 height values across the investigated range. To estimate the regression-based optimum height, the fitted quadratic curve was evaluated at 1000 equally spaced heights within the analysed range, and the minimum predicted weight

was selected. No explicit outlier removal or influence screening was applied; all available cases were retained. Finally, a genetic algorithm (GA)EC is used to search for minimum-weight solutions and to provide an independent check
for comparison with the regression-derived optima.

Results and Discussion



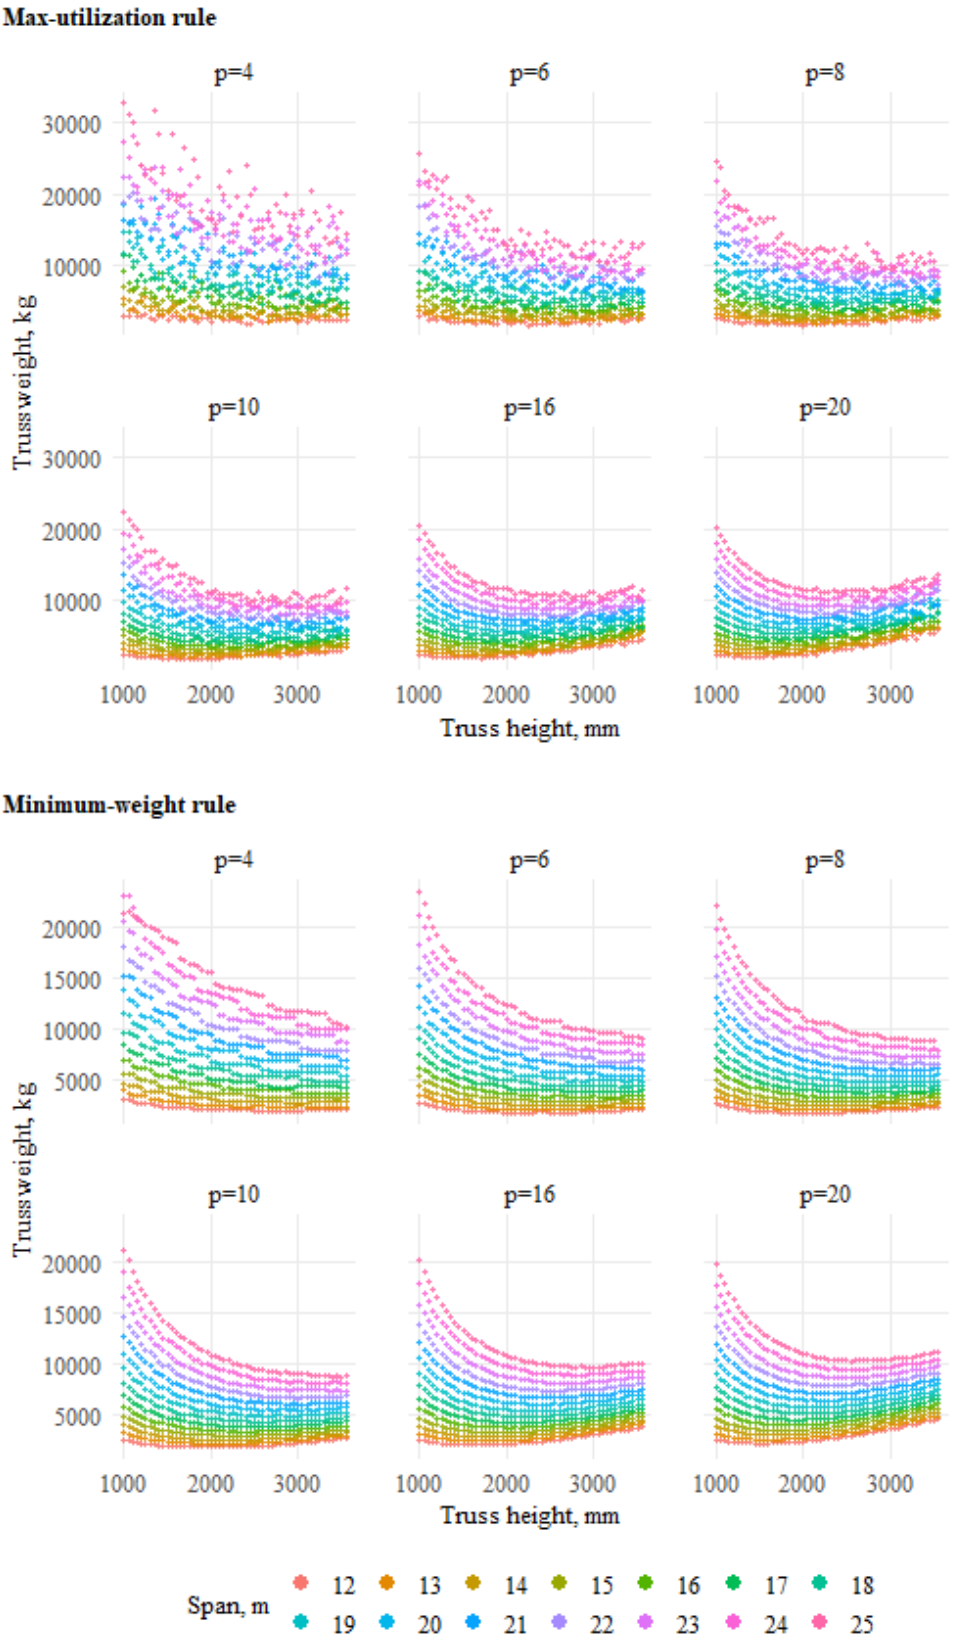
The study generates a large amount of data, the analysis of which requires a systematic approach. To achieve research objectives, data are analysed sequentially using appropriate methods. At first the results of the two sizing algorithms are compared and analysed. Then data are compared by support types, initial cross section and iterations of truss calculations. Following initial data analysis, the sizing approach comparison and regression is performed. Finally, trusses are recalculated at the regression-optimum heights and GA is used to check selected cases.

Sizing algorithm comparison

Visual analysis indicates clear differences between the two catalogue-based sizing rules: maximum utilization and minimum profile weight. For each member, both rules select among profiles that satisfy Eurocode 3 checks. Figure 3 shows that the minimum-weight rule yields lower total truss weight and a smaller spread of results than the maximum-utilization rule for sizing approach A2. The difference is statistically significant (two-sided paired Wilcoxon signed-rank test on matched cases, $p < 0.05$). The weight dispersion increases with span for both sizing rules, reflecting the combined effect of buckling-governed compression design and discrete profile availability in the catalogue.

Figure 3

Truss weight distribution by span for two member-sizing rules



Support sensitivity and iterative coupling

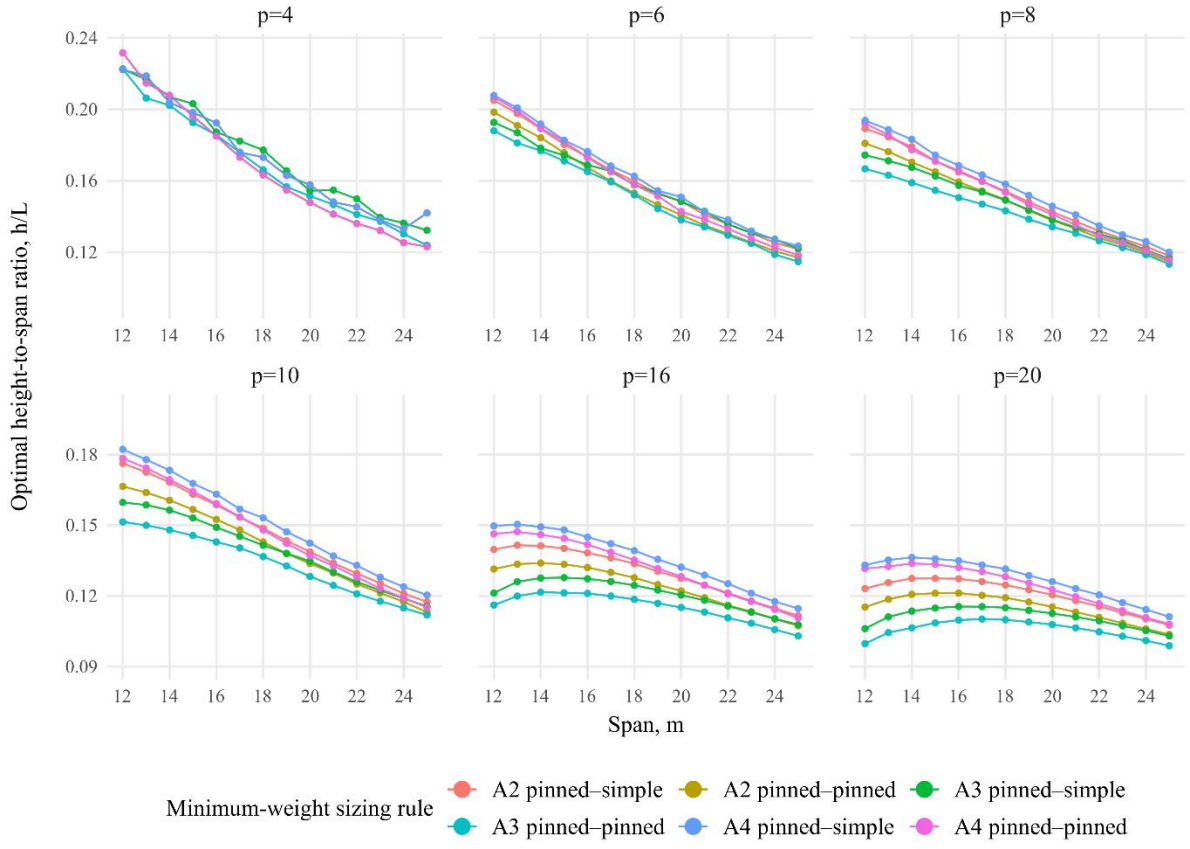
Supports boundary conditions influence the distribution of internal forces and displacements and therefore affect the iterative cross-sectional coupling between FEM analysis and catalogue-based sizing. When one support is modelled as pinned and the other as simple, the coupled analysis-sizing procedure stabilizes rapidly, and the final member set is largely insensitive to the initial cross-sectional area. In contrast, when both supports are pinned, the increased kinematic freedom leads to a stronger redistribution of forces between iterations, and the final outcome becomes more sensitive to the selected sizing rule, sizing approach, and panel count. For pinned–pinned supports, convergence is weaker; using $\Delta W/W$ between the last two stored iterations, an example A3 subset shows ~90% stabilized, while remaining cases exhibit small residual changes ($\leq$ ~0.2%), increasing dispersion.

Figure 4 illustrates this sensitivity by showing how the response changes across panel counts and spans under the alternative sizing rules. In the max-utilization rule, the distribution of results exhibits markedly higher scatter and less stable trends, indicating a more irregular interaction between discrete profile replacement and global stiffness redistribution. The minimum-weight rule produces smoother trends and noticeably reduced dispersion, suggesting more consistent convergence of the coupled procedure. The effect is most pronounced for sizing approaches that enforce stronger catalogue discretization or chord uniformity constraints, where profile 'jumps' introduce larger stiffness changes between iterations. Overall, the support configuration is therefore a key factor in the robustness of optimal-solution identification, and the pinned-pinned case represents the more demanding scenario for sizing-rule comparisons and subsequent regression-based optimum extraction.

Figure 4
Truss weight trends across panel counts and spans for two sizing rules

Regression optimum and comparison by GA

To identify minimum-weight configurations for each truss case, the relationship between total truss weight and truss height is evaluated across the investigated height range. For each fixed combination of span, panel count, support configuration, sizing approach, and sizing rule, a quadratic regression was fitted to the weight-height response, and the minimum of the fitted



curve is interpreted as the regression-based optimum height. The quality of the fitted optimum depends on the smoothness of the underlying response and thus reflects the stability of the coupled FEM–sizing iterations (final iteration used consistently; non-stabilized cases not excluded). Cases with higher dispersion, most pronounced under the max-utilization sizing rule and more restrictive catalogue settings, yield less reliable minima than cases where weight varies smoothly with height. For the 84 fitted models, the coefficient of determination ranged from R^2=0.3472 to 0.9837, with adjusted R^2 values from 0.3206 to 0.9830 (mean R^2=0.8284; median R^2=0.8697). In all models, the quadratic coefficient was positive and statistically significant (p<0.05), supporting the use of a convex quadratic curve to estimate the minimum weight. Because no explicit outlier removal or influence diagnostics were applied, sensitivity to outliers is reflected indirectly in the lower R^2 values and the wider scatter of the more irregular response cases. For selected cases, GA optimisation is used as a check for the regression-derived optima; however, as a metaheuristic it does not guarantee a global optimum, and systematic deviation statistics over multiple runs are left for future work.

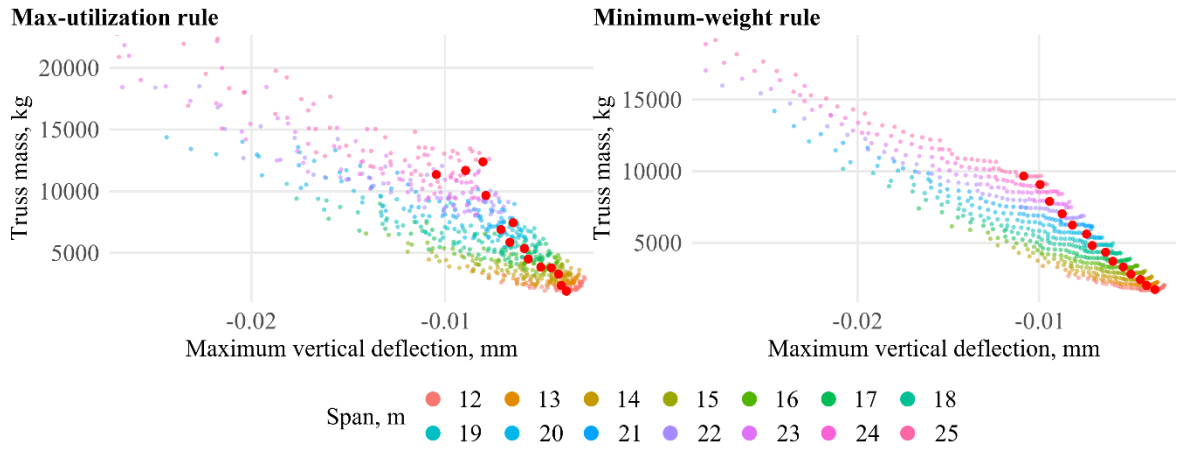
The resulting optimal height-to-span ratios are summarized in Figure 5. The optimal h/L values exhibit distinct trends for different panel counts, while for a fixed panel count the optimal ratio varies smoothly with span. Across the investigated design space, the trends remain consistent between sizing approaches, although the max-utilization rule produces a wider scatter of optimal ratios than the minimum-weight rule.

A complementary interpretation of the optimum is provided by the deflection response shown in Figure 6, where regression-optimum cases are highlighted relative to the full set of evaluated heights. Increasing truss height initially reduces deflections substantially, but beyond a certain range additional height yields diminishing stiffness benefits while the total weight continues to increase. The regression-based optimum is located near this transition, indicating a balance between stiffness gain and added material demand. The clearest span-dependent correlations of near-optimal cases are observed for the minimum-weight sizing rule, whereas max-utilization sizing exhibits higher dispersion and less stable optima, consistent with the previously observed sensitivity of discrete profile selection under buckling-governed compression design.

Figure 5

Optimal height-to-span ratio trends across spans and panel counts

Discussion and implications



The results confirm that 'optimal' Pratt truss solutions are influenced not only by topology and geometry, but also by sizing mechanics. This is particularly evident in the treatment of buckling in compression members and in the discreteness of catalogue sections. A key finding is the different robustness of trends produced by the two profile-selection rules. Selecting profiles by minimum weight (while satisfying Eurocode 3) yields a smoother weight–height response and more coherent near-optimal solutions across spans and panel counts. This occurs because the minimum-weight rule typically moves between neighbouring sections within the same profile family, leading to smaller stiffness changes between iterations. Consequently, the coupled analysis–sizing loop stabilizes more reliably, which supports regression-based optimum identification.

In contrast, selecting profiles by maximum utilization can produce higher scatter and less stable optima, even though utilization-based selection is widely used in member sizing workflows. The underlying mechanism is most apparent in compression members. For tension members, utilization is closely linked to axial resistance and cross-sectional area, and therefore high utilization typically corresponds to an efficient use of material. For compression members, however, the governing resistance may be controlled by buckling rather than yielding, and buckling resistance depends strongly on section shape through stiffness and radius of gyration. Consequently, a high-utilization compression member may still be relatively heavy because it satisfies buckling through geometry rather than efficient mass distribution. In addition, utilization-based selection can encourage switching between different section families (for example between open and closed sections) because utilization does not inherently penalize mass. Such jumps may cause large changes in stiffness and force redistribution, which amplifies the sensitivity of the coupled iterations and contributes to the observed dispersion. From a methodological perspective, this supports the broader view in buckling-constrained optimization research that compression-member sizing requires dedicated handling, rather than applying the same selection logic used for tension members. In practical terms, weight-optimal sizing workflows should prioritize weight and limit unnecessary cross-family switching for compression-critical members, especially when results are used for regression-based generalization.

The study also demonstrates that the number of panels has a dual role in optimal solution identification: it governs both the absolute weight level and the predictability of response trends. Trusses with a small number of panels exhibit more irregular behaviour, and small geometric changes can lead to disproportionate changes in member angles and load paths. This effect makes low-panel configurations more sensitive to discrete profile updates, which is reflected in larger scatter of the optimal height-to-span ratios derived. As panel count increases, the larger number of members allows greater force redistribution, and the global response varies more smoothly with height and span. This makes the regression-based optimum identification more stable and the dependence of optimal h/L on span more clearly traceable within each panel-count group. This increased predictability comes at the cost of more members and greater total weight, so additional panels represent a trade-off between material demand and design robustness. This trade-off is important for early-stage design decisions, where the ability to predict near-optimal geometry reliably can be as valuable as minimizing mass strictly.

Figure 6

Weight and deflection trends with regression-optimum cases highlighted

Manufacturing-oriented constraints further shape this balance. When chord uniformity is enforced by assigning uniform upper- and lower-chord profiles along the span, the solution space becomes more restricted, and the structure carries larger reserves than the unconstrained optimum. This is reflected in reduced sensitivity and a narrowing of differences between sizing rules, because the uniform-chord

constraint drives the design away from locally efficient member-by-member solutions and reduces the attainable utilization level in parts of the structure. While such constraints increase weight, they also improve constructability and reflect common practice. For applications aimed at industry use, this underlines the importance of reporting not only theoretical optima but also optima under practical fabrication constraints, since these are the configurations that can be implemented without substantial redesign effort.

Several limitations frame the applicability of the presented trends. The analysis considered a single load case and neglected self-weight, which may shift the absolute optimum, especially for longer spans where self-weight makes up a larger share of the total load. Multiple load combinations would also be expected to reduce utilization levels and increase design reserves, which could dampen some of the sharpness of the identified optima and may reduce the contrast between sizing rules. At the same time, the adoption of Eurocode 3 checks and discrete catalogues is a deliberate choice that prioritizes practical relevance over idealized continuous-stress formulations. The design space was limited to common spans and planar configurations; beyond this range, alternative structural forms and spatial systems may become more competitive, especially when dense panel and bracing grids provide stiffness and load distribution with smaller overall depth. Extending the present approach to longer spans and spatial truss systems, testing sensitivity to material grade, and expanding the load cases are natural next steps before generalizing the regression relationships into design charts or predictive models.

From an application standpoint, the present findings provide two immediate implications. First, there is no universal ‘rule-of-thumb’ optimal h/L for all Pratt trusses; the optimum depends systematically on panel count and span, and this dependency remains visible across sizing approaches. Second, robust pre-design guidance is more likely from workflows that prioritize minimum-weight feasible catalogue selection and explicitly include constructability constraints rather than relying only on utilization maximization. With further generalization across load scenarios and material grades, the identified relationships can be converted into practical charts or regression-based equations to guide early-stage selection of near-optimal geometry and narrow the design space before detailed engineering.

Conclusions

1. The results confirm that optimal Pratt truss solutions are strongly influenced by the adopted member-sizing strategy, particularly for buckling-governed compression members. Catalogue selection based on minimum profile weight produces clearer trends and substantially lower scatter than selection based on maximum utilization, indicating that utilization-driven sizing can obscure systematic optimality patterns in discrete, buckling-controlled design.
2. Panel count is a primary factor governing both structural behaviour and the predictability of optimal solutions. The most irregular responses were observed for 4 and 6-panel trusses, while 8-panel trusses showed intermediate behaviour and the trends became clearly smoother from 10 panels onward. This improved predictability comes at the cost of increased member count and total weight.
3. The optimal height-to-span ratio is not a single universal value; within the investigated design space, the optimal h/L was approximately 0.10–0.23. The highest values occurred in short-span trusses with low panel counts, while the lowest values occurred in long-span trusses with high panel counts. Across the investigated sizing approaches, the same overall dependency on panel count and span was preserved, while the sizing approach mainly shifted the absolute level and dispersion of the optimal ratio.
4. Near-optimal cases occur close to a transition in structural response where increasing truss height yields diminishing stiffness benefits while total weight begins to increase due to compression-member sizing requirements. The alignment of optimal cases across spans suggests that, within the investigated design space, the identified relationships can support interpolation-based pre-design estimation of near-optimal Pratt truss geometry and response.

Abstract
The aim of this study is to evaluate the agreement and scale-dependent differences between a regional Latvian GNSS-based ionospheric time series and widely used Global Ionosphere Map (GIM) products. The regional model is derived from dual-frequency GPS and Galileo observations collected by a dense national Continuously Operating Reference Station (CORS) network, providing vertical total electron content (VTEC) estimates at ionospheric pierce point locations without spatial smoothing or regional averaging. Slant total electron content (STEC) is computed from carrier-phase geometry-free combinations using standard procedures, and converted to VTEC using a single-layer ionospheric approximation suitable for mid-latitude conditions. Short-term ionospheric variability is additionally characterized using the Rate of TEC Index (ROTI), derived consistently from the same observation set. This approach preserves both the dominant diurnal ionospheric behaviour and finer-scale temporal variability resolved by the dense observation network. An independent comparison is performed using GIM products from CODE, ESA, IGS, and JPL. These models are interpolated to the local ionospheric pierce point geometry, enabling direct comparison without additional calibration. The analysis is based on over one million matched data points and includes root-mean-square error, correlation metrics, and bias evaluation. Results indicate that global models capture the large-scale diurnal evolution of VTEC but significantly smooth short-term and regional variability. While correlations remain moderate to strong, systematic offsets and increased dispersion are observed, particularly during disturbed conditions. The findings highlight the importance of dense regional GNSS networks for capturing ionospheric variability at enhanced temporal and spatial resolution.
Keywords: GNSS observations, ionospheric modelling, TEC, GIM, CORS networks.

Introduction

The terrestrial ionosphere constitutes a variable and frequency-dependent propagation environment for Global Navigation Satellite System (GNSS) signals. Spatial and temporal variations in electron density introduce dispersive signal delays that directly affect GNSS observations and derived products (Hofmann-Wellenhof et al., 2007). Although dual-frequency GNSS techniques allow the dominant first-order ionospheric effect to be removed from positioning solutions, the ionosphere itself remains a highly dynamic geophysical medium whose behaviour cannot be fully described by simplified correction models. Consequently, the representation and interpretation of ionospheric total electron content (TEC) continue to play a key role in both geodetic and ionospheric research.

At the global level, ionospheric conditions are commonly described using Global Ionosphere Maps (GIMs), which provide gridded representations of vertical total electron content (VTEC) over the Earth's surface. These products are routinely generated in the IONEX format by the International GNSS Service (IGS) and its associated analysis centres and serve as a standard reference for a wide range of applications, including long-term climatological studies, model intercomparison, and validation of ionospheric correction approaches (Schaer et al., 1998). By construction, GIM products offer a consistent and globally homogeneous view of the ionosphere.

However, the global nature of GIMs inherently limits their spatial and temporal resolution. The combination of globally distributed input data, regular grid representations, and modelling constraints leads to a smoothed depiction of ionospheric structure (Hernandez-Pajares et al., 1997). While such smoothing is advantageous for capturing large-scale ionospheric behaviour, it may obscure short-term variations and regional-scale features that arise from localized drivers and rapidly evolving ionospheric processes.

This limitation is particularly relevant in mid-latitude regions, where the ionosphere is shaped by a combination of solar radiation, geomagnetic forcing, and thermospheric dynamics. In these regions, the ionospheric response is characterized by pronounced diurnal cycles, seasonal variability, and the occurrence of medium-scale disturbances, such as traveling ionospheric disturbances and localized gradients (Hernandez-Pajares et al., 2006; Emardson et al., 2013). Although such effects are generally less extreme than those observed in equatorial or auroral zones, they can still produce significant regional variability that may not be fully resolved by global models.

Recent advances in GNSS infrastructure have led to the deployment of dense Continuously Operating Reference Station (CORS) networks and to the routine availability of multi-constellation observations. These developments provide the opportunity to investigate ionospheric behaviour at spatial and temporal scales that extend beyond the resolving capability of global ionospheric maps (Otsuka et al., 2002). In particular, the combined use of GPS and Galileo dual-frequency measurements improves observation geometry and enables robust estimation of slant and vertical TEC at the level of

individual signal paths, provided that hardware-dependent biases and inter-system effects are handled consistently.

Within this context, regional GNSS-based ionospheric models offer a valuable complement to global products. Rather than replacing global ionospheric maps, such regional representations allow the examination of how locally derived TEC estimates relate to globally modelled ionospheric fields and to what extent regional observations capture variability that is smoothed in global products. This perspective is especially relevant for regions with dense GNSS coverage, where observation geometry supports high temporal and spatial resolution.

The present study introduces a regional GNSS-based ionospheric representation developed for Latvia and investigates its relationship with established Global Ionosphere Map products. Slant TEC is derived from carrier-phase observations using standard bias handling and phase leveling procedures and is subsequently mapped to vertical TEC using a single-layer ionospheric approximation suitable for mid-latitude conditions. Short-term ionospheric variability is described using the Rate of TEC Index (ROTI), derived consistently from the same observation set.

A systematic comparison is performed using multiple GIM products generated by different IGS analysis centres, including CODE, ESA, IGS, and JPL. Global maps are interpolated in space and time to the ionospheric pierce point geometry of the regional GNSS observations, enabling a direct comparison without calibration or bias alignment. A representative Latvian CORS station is used to illustrate differences in temporal behaviour and variability between regional and global ionospheric representations.

The aim of this study is to evaluate the agreement and scale-dependent differences between a regional Latvian GNSS-based ionospheric time series and widely used Global Ionosphere Map (GIM) products generated by different IGS analysis centres. To achieve this aim, the following tasks were defined: (1) to derive a regional VTEC time series from dual-frequency GPS and Galileo observations collected by the Latvian CORS network; (2) to interpolate selected GIM products (CODE, ESA, IGS and JPL) to the local ionospheric pierce point geometry; (3) to compare regional and global VTEC estimates using statistical indicators including bias, RMSE and correlation; and (4) to assess the ability of global models to represent regional and short-term ionospheric variability.

Materials and Methods

Regional GNSS observation environment

The regional ionospheric model analysed in this study is based on observations from the Latvian national CORS network. The network offers dense and spatially well-distributed GNSS coverage across the territory of Latvia, providing favourable conditions for the investigation of ionospheric variability at regional scales. The typical inter-station spacing is sufficiently small to sample ionospheric conditions with a spatial resolution that exceeds that of global ionospheric products.

GNSS observation data are available in RINEX version 3.04 and include dual-frequency measurements from the GPS and Galileo constellations. The data set comprises carrier-phase and pseudorange observations, together with the auxiliary information required for satellite geometry reconstruction. Observations are sampled at a 1 second interval, allowing the analysis of both longer-term ionospheric evolution and short-term temporal variability. Receiver coordinates are extracted from the RINEX headers and are assumed to remain constant throughout each daily observation session.

The use of a multi-constellation data set enhances ionospheric sampling and reduces dependence on individual satellite geometries. At the same time, it introduces additional complexity related to inter-system biases and constellation-specific characteristics. These aspects are addressed during the modelling procedure and do not affect the definition of the observational environment described here.

Latvia is located in the mid-latitude region of Northern Europe, where ionospheric behaviour is primarily governed by solar radiation, geomagnetic activity, and thermospheric dynamics. Over this region, the ionosphere typically exhibits a pronounced diurnal cycle, clear seasonal variability, and moderate short-term disturbances. Although extreme ionospheric phenomena associated with equatorial or auroral processes are generally absent, mid-latitude structures such as travelling ionospheric disturbances and localized gradients occur regularly (Hernandez-Pajares et al., 2006; Emardson et al., 2013).

From a modelling perspective, the Latvian region represents an intermediate test environment in which global ionospheric models are expected to capture the dominant large-scale behaviour of TEC, while finer-scale and short-term variations may remain unresolved. This makes the region particularly suitable for comparative analysis between global ionospheric maps and regional GNSS-based ionospheric representations.

Representative station selection

To illustrate the characteristics of the regional ionospheric model and to facilitate a transparent comparison with global products, results from the CORS station Aizpute (AIZP) are examined in detail. This station is representative of the Latvian network with respect to data continuity, receiver performance, and geographical setting. Its location sufficiently far from the network boundaries reduces potential edge effects in regional analyses.

Time series derived from AIZP are used as a reference example in the results section to demonstrate the temporal evolution of VTEC, the presence of short-term variability, and systematic differences between locally derived ionospheric estimates and global ionospheric products. While AIZP is employed for illustrative purposes, the regional ionospheric model itself is based on observations from the full CORS network.

TEC estimation methodology

The estimation of ionospheric TEC from GNSS observations exploits the dispersive nature of the ionosphere, whereby signal delays depend on the transmitted frequency. Dual-frequency carrier-phase measurements from GPS and Galileo provide a highly sensitive means of isolating the ionospheric contribution to signal propagation, independent of geometric range and clock effects (Hofmann-Wellenhof et al., 2007).

In this study, ionospheric information is extracted using the geometry-free combination of carrier-phase observables. This combination eliminates non-dispersive terms common to both frequencies and retains the frequency-dependent ionospheric delay, making it well suited for TEC estimation (Ciraolo, 2007). The geometry-free carrier-phase combination is expressed as Equation (1):

$$L_{GF} = \lambda_1 \Phi_1 - \lambda_2 \Phi_2 \qquad (1)$$

where Φ_1 and Φ_2 denote the carrier-phase observations at frequencies f_1 and f_2, respectively, and λ_i are the corresponding signal wavelengths. The resulting observable is directly proportional to the slant total electron content (STEC) along the satellite–receiver line of sight, as given in Equation (2):

$$STEC = \frac{f_1^2 f_2^2}{40.3\left(f_1^2 - f_2^2\right)} L_{GF} \qquad (2)$$

Carrier-phase observations are preferred over code measurements due to their superior precision, which is essential for resolving subtle ionospheric variations at short temporal scales.

Despite their low noise characteristics, carrier-phase measurements are affected by unknown phase ambiguities and hardware-dependent biases. To ensure physically consistent TEC estimates, satellite-specific observable biases are applied prior to TEC computation, and receiver-dependent biases are estimated from the data using robust statistical approaches (Su et al., 2021). To preserve the precision of carrier-phase-derived STEC while maintaining consistency with code-based observables, phase leveling is applied over continuous observation arcs, as described by Equation (3):

$$STEC_{lev} = STEC_{\phi} + \Delta_{bias} \qquad (3)$$

For comparison with global ionospheric products, slant TEC estimates are mapped to vertical TEC using a single-layer ionospheric approximation, as defined in Equation (4), with an effective shell height of 450 km (Li et al., 2020). The elevation-dependent mapping function is given in Equation (5):

$$VTEC = STEC \cdot M^{-1}(e) \qquad (4)$$

$$M(e) = \left(1 - \left(\frac{R_E cose}{R_E + H_{ion}}\right)^2\right)^{-\frac{1}{2}} \qquad (5)$$

Vertical TEC estimates are associated with ionospheric pierce point (IPP) locations. No spatial gridding or averaging is applied, which allows a direct comparison with global ionospheric products after interpolation. Short-term ionospheric variability is characterised using the Rate of TEC Index (ROTI) (Wanninger, 2004; Cherniak et al., 2014).

Validation and comparison framework

Independent validation is performed using GIM products generated by several IGS analysis centers, including CODE, ESA, IGS, and JPL. These products are distributed in the IONEX format and represent global VTEC fields on regular latitude–longitude grids (Schaer et al., 1998; Garcia-Rigo et al., 2011).

GIM-based VTEC values are interpolated spatially and temporally to the IPP locations and observation epochs of the regional GNSS data. Differences between regional and global VTEC estimates are evaluated using standard statistical metrics, including mean bias, root-mean-square error, mean absolute error, and the Pearson correlation coefficient. Aggregation over large data volumes ensures the statistical robustness of the comparison.

Results and Discussion

Temporal behaviour of regional VTEC

The regional GNSS-based ionospheric model yields continuous VTEC time series at ionospheric pierce point (IPP) locations for all stations within the Latvian CORS network. At the individual station level, the derived VTEC values exhibit a well-defined and physically plausible diurnal pattern, characterised by low nighttime levels and a pronounced daytime enhancement associated with solar-driven ionisation processes.

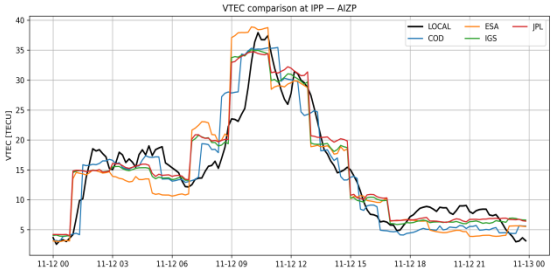

Figure 1 illustrates the temporal evolution of VTEC at the representative station AIZP. The locally derived VTEC time series captures the dominant large-scale diurnal behaviour while simultaneously resolving short-term temporal variations. The absence of discontinuities or step-like features indicates that bias handling and phase-levelling procedures provide a stable and internally consistent reference for absolute TEC estimation over extended observation periods.

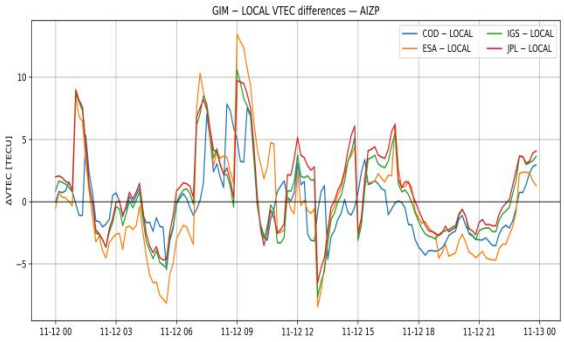
Comparison with Global Ionosphere Map products

The regional VTEC estimates are compared with GIM products from CODE, ESA, IGS, and JPL

following spatial and temporal interpolation of the global models to the IPP geometry of the regional observations. All considered global products successfully reproduce the dominant diurnal variation observed in the regional model, demonstrating overall consistency at broad spatial and temporal scales.

Figure 1
Comparison of locally derived VTEC and Global Ionosphere Map products (CODE, ESA, IGS, JPL) at the ionospheric pierce point for CORS station AIZP



At the same time, systematic differences between the regional and global representations are evident throughout the day. In particular, the GIM-based time series display markedly smoother temporal behaviour, especially during intervals characterised by rapid VTEC changes. This behaviour reflects the coarser spatial resolution and limited temporal sampling inherent to global ionospheric products and contrasts with the higher-frequency variability resolved by the dense regional GNSS network.

VTEC differences and distribution characteristics

Differences between GIM-derived VTEC and locally estimated VTEC are computed at the individual observation level and analysed over the full observation period. Figure 2 illustrates the statistical differences between GIM-derived and locally estimated VTEC at station AIZP. The resulting distributions reveal persistent offsets between the regional model and each global product, together with an increase in dispersion during periods of enhanced ionospheric variability.

Figure 2
Statistical differences between GIM-based and locally derived VTEC for CORS station AIZP

Although the magnitude and sign of the bias differ slightly among the individual GIM products, the overall structure of the differences remains similar. This consistency suggests that the observed discrepancies primarily reflect differences in spatial and temporal resolution rather than shortcomings specific to any single global ionospheric model.

Statistical assessment of model agreement

Quantitative metrics summarising the agreement between the regional VTEC estimates and the four GIM products are presented in Table 1. The table reports the root-mean-square error (RMSE), the Pearson correlation coefficient r, and sample size.

Table 1
Statistical comparison between the regional VTEC model and selected Global Ionosphere Map (GIM) products at station AIZP

Model	RMSE (TECU)	r	N
CODE	12.722	0.570	1096,923
ESA	13.319	0.542	1096,923
IGS	13.109	0.556	1096,923
JPL	13.360	0.555	1096,923

All global products exhibit a negative mean bias with respect to the regional model, indicating systematically lower VTEC values in the GIM solutions. Correlation coefficients exceed 0.54 for all products, pointing to good temporal agreement at large scales. Nevertheless, the RMSE values highlight the magnitude of residual differences associated with ionospheric structures that are not fully resolved by global models.

Resolution-dependent effects

The comparative analysis reveals a clear scale-dependent separation between regional and global ionospheric representations. While global models provide a reliable depiction of the background ionospheric state and its diurnal evolution, the regional GNSS-based model resolves additional variability at shorter temporal and spatial scales.

These results indicate that differences between regional and global VTEC estimates should not be interpreted as modelling errors in a strict sense. Rather, they reflect the inherent trade-off between global coverage and model resolution. Dense regional GNSS observations therefore provide complementary information that is not fully captured by globally smoothed ionospheric products.

Conclusions

1. The aim of the study was achieved through observation-level comparison of a regional Latvian GNSS-derived VTEC time series with four Global Ionosphere Map products and assessment of their statistical agreement and scale-dependent differences.
2. The results show that global ionospheric models reliably reproduce the large-scale diurnal evolution of vertical total electron content, whereas regional GNSS observations capture additional short-term and regional-scale variability.

3. Consistent systematic differences between regional and global VTEC estimates were identified for all analysed GIM products, indicating resolution-dependent smoothing effects rather than deficiencies in individual global models.
4. Statistical evaluation based on more than one million matched observations demonstrated moderate to strong temporal agreement between regional and global ionospheric representations, together with residual differences linked to unresolved regional ionospheric structures.
5. The findings underline the complementary nature of regional GNSS-based ionospheric modelling and global ionospheric products and confirm the importance of dense regional GNSS networks for applications requiring enhanced temporal and spatial resolution of ionospheric behaviour.

APPLICATION OF THE LBTU METHOD FOR DEFORMATION MONITORING OF A TUNNEL DURING CONSTRUCTION

***Edgars Kraskevičs, Armands Celms**
Latvia University of Life Sciences and Technologies, Latvia
*Corresponding author's e-mail: ekras@inbox.lv

Abstract
In modern construction practice, deformation monitoring is applied as a form of quality control for construction works. Such monitoring is important not only after a structure has been commissioned, but also during the actual process of structural erection. One of the methods used for this purpose is the LBTU (laser-based tracking utilisation) method, which is based on distance measurements performed using a laser rangefinder. Depending on the measuring equipment employed, deformations can be recorded with an accuracy of approximately 1–2 mm. During the construction of bridges and tunnels, backfilling operations are almost always required. When soil is compacted, the weight and pressure of the fill material induce stresses within the structural elements of the infrastructure facility. Furthermore, the process of layered soil placement during construction often imposes greater loads on the structure than the static soil pressure acting during the operational phase. Backfilling operations involve the use of heavy machinery, which generates dynamic loads. Water is also applied to increase soil density during compaction, further intensifying these effects. As a result, construction-stage loads frequently exceed those experienced during exploitation. For this reason, deformation monitoring during construction represents an effective quality control strategy and a safety tool for contractors. The application of the LBTU method during tunnel backfilling at a construction site in Riga demonstrated the practicality of the method and the reliability of the obtained data. Such monitoring does not significantly increase construction costs, yet it can improve quality and prevent critical overloads and structural deformations caused by human factor.
Keywords: deformation monitoring, LBTU method, rangefinder, tunnel backfilling.

Introduction

During the construction of infrastructure facilities, monitoring of structural deformations during earthworks represents a critical aspect of ensuring structural safety and performance. One of the most sensitive stages of construction is the backfilling process, during which the structure is subjected to both permanent and temporary loads associated with construction activities. Improper sequencing of operations or localised concentration of loads may lead to undesirable deformations that can affect the structural behaviour and long-term serviceability of the facility.

In recent years, increasing attention within the construction industry has been directed towards operational monitoring techniques capable of detecting geometric changes in structural elements in near real time and enabling the early identification of potentially hazardous deformation trends (Wang et al., 2024). This task becomes particularly relevant in the case of lightweight engineering solutions, such as tunnels incorporating corrugated steel shells, where structural performance is strongly influenced by the interaction between the structure and the surrounding soil during the backfilling process.

One practical approach to addressing this challenge involves the application of simple and cost-effective instrumental monitoring methods capable of providing sufficient measurement accuracy while maintaining low implementation costs. The use of laser distance meters for deformation monitoring represents one such method, allowing efficient and continuous acquisition of geometric data directly on the construction site.

The object of observation is a tunnel constructed from a combination of materials: a reinforced concrete base and walls, together with a corrugated metal roof. The roof has been intentionally designed with a curved profile and stiffening ribs in order to increase its load-bearing capacity while using a minimal amount of material. This engineering solution was selected due to the relatively shallow groundwater conditions at the site. In order to accommodate the tunnel within the limited space between the roadway and the groundwater level, it was necessary to minimise the height of the embankment above the tunnel roof.

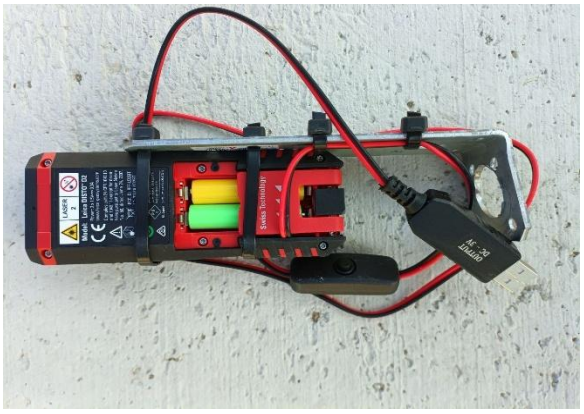
A corrugated steel roof effectively distributes loads without significant deformation and allows a reduction in the thickness of the backfill layer beneath the roadway.

In engineering geodetic practice, both classical surveying methods and modern automated monitoring systems are employed for deformation monitoring (Wulf Schubert et al., 2002). The most commonly used approaches include high-precision total station measurements, levelling, GNSS observations, inclinometer monitoring, as well as various sensor-based systems utilised within structural health monitoring frameworks. The selection of an appropriate method depends on the required accuracy, site conditions, the feasibility of measurement automation, and economic considerations. For structures under construction, particular importance is given to methods that can be rapidly deployed, do not require highly specialised personnel, and enable high-frequency data acquisition in near real-time conditions (Ma et al., 2023).

The aim of this study is to analyse the deformation behaviour of a tunnel structure during the backfilling stage and to evaluate the effectiveness of laser-based distance measurements for operational monitoring of geometric changes under construction site conditions.

Materials and Methods

The tunnel backfilling process was carried out in two stages. The first stage proceeded up to the elevation at



which the reinforced concrete structure terminates and transitions into the steel roof. Consequently, the laser rangefinders were installed at the maximum backfill level corresponding to the completion of the first stage. The second stage of backfilling was scheduled to be undertaken at a later date following the completion of other construction activities. During this stage, the laser sensors are intended to be relocated to the tunnel roof along the tunnel centreline, where the greatest structural deformations are anticipated to occur.
At the time of writing, measurements from the second stage monitoring campaign are not yet available and are therefore excluded from the present analysis. This is justified by the fact that the primary objective of this study is not the assessment of tunnel deformations themselves, but rather the evaluation and demonstration of the Laser-Based Tracking Utilisation (LBTU) methodology as a deformation monitoring technique.

Figure 1
Backfilling of the tunnel

Backfilling of the tunnel must be carried out sequentially. The designer calculated the loads exerted by the soil on the tunnel structure and specified that the backfilling process should be performed in stages, alternately loading one side of the tunnel and then the other. The soil is placed and compacted in layers of approximately 0.5-meter thickness, backfilling process is shown in Figure 1.
Soil represents a static load exerting continuous pressure on the structure, whereas construction equipment used by the contractor such as excavators, rollers, and compactors constitutes a dynamic load (Singh & Mandal, 2019). As this machinery moves across the site, it may create localised concentrations of force that can affect the structural behaviour of the tunnel. Additional loading is introduced by water used during soil compaction. Although this load is temporary and will disappear after construction works are completed, it represents a significant additional factor influencing structural deformation during the construction phase.
In order to record and monitor structural deformations of the tunnel, the LBTU method was selected due to its simplicity of use and low implementation cost. The method is based on distance measurements obtained using a laser rangefinder. Such instruments are widely known and readily available to construction professionals worldwide. More advanced models provide wireless connectivity to a computer and programmable settings that allow the instrument to operate in an automated measurement mode.
The laser distance meter Leica DISTO D2 was employed as the primary measurement instrument, with technical characteristics suitable for monitoring small-scale deformations in construction applications. According to the manufacturer's specifications, the device provides a measurement accuracy of ±1.5 mm and an operating range of up to 100 m, and supports data transmission via bluetooth, enabling its integration into an automated data acquisition system (Product Data Sheet Leica DISTOTM D2, n.d.)

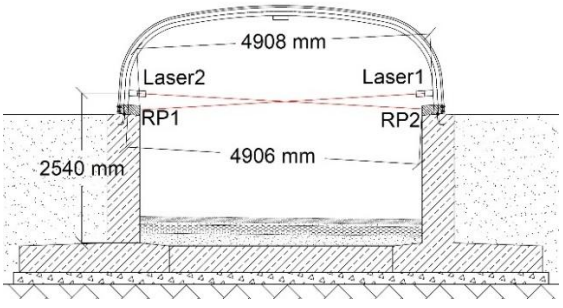
Figure 2
Laser rangefinder equipped with an alternative power supply system

In the present study of tunnel deformation monitoring, two identical laser distance meters were used. This model is well suited for automated monitoring and large-volume data acquisition due to the possibility of connecting the device to a laptop computer and collecting measurements continuously throughout the working day. Figure 2 shows how each distance meter was modified to operate from an external power supply in order to enable extended autonomous operation and was equipped with a mounting system.
One of the principal limitations of the proposed monitoring system is associated with the current capabilities of the manufacturer software. At present, the software does not support the simultaneous connection of multiple laser rangefinders to a single computer, nor does it provide integration with a central communication hub capable of transmitting measurement data to a remote server via the internet.
As a consequence, two separate laptop computers equipped with independent bluetooth communication modules were required to operate the two laser rangefinders used in this study. Under the current system architecture, scaling the monitoring network to

ten sensors would necessitate the use of ten individual computers, which would be both impractical and economically inefficient.

Future software development could substantially improve the scalability of the method. In particular, the ability to connect multiple laser rangefinders to a single computer or to a dedicated data acquisition hub would significantly simplify system deployment and operation. Such an enhancement would enable the method to be readily applied to larger monitoring networks and would broaden its potential application to large-scale civil engineering and infrastructure projects.

Figure 3



Rangefinder installed on the tunnel and modified for external power supply

Using a bolted mounting assembly, the laser rangefinder was securely installed on the tunnel structure, as shown in Figure 3. A schematic representation of the laser sensor arrangement is provided in Figure 4, illustrating the locations of the monitoring instruments within the tunnel structure.

Figure 4

Layout of the control points and laser distance meters

The laser rangefinders were calibrated and certified by an accredited metrological laboratory prior to their deployment in the monitoring programme. This procedure was undertaken to ensure the reliability and traceability of the measurements, as well as to verify that the measurement uncertainty specified by the manufacturer corresponded to the actual performance characteristics of the instruments.

To establish the initial reference point for deformation monitoring, baseline measurements from the distance meters were recorded under static conditions prior to the commencement of backfilling works. As the intensity of construction activity was relatively low, the automatic measurement interval was set to one measurement per minute.

During the tunnel backfilling operations, continuous monitoring of structural deformations was carried out using two laser distance meters installed in accordance with the arrangement shown in Figure 5. Measurements were performed automatically at one-minute intervals throughout the entire duration of the backfilling works.

Initial distance values were recorded prior to the commencement of backfilling, when the structure was in a stable, unloaded condition. The average baseline distance was 4,909 meters for measurement point RP1 and 4,908 meters for measurement point RP2.

Results and Discussion

The proposed method combines the principles of conventional deformation monitoring techniques, such as tape-based distance measurements and precise levelling, with automated surveying technologies, including electronic total stations and robotic total stations (Ma et al., 2023; Wang et al., 2024). This integration enables continuous or semi-continuous monitoring while reducing the amount of on-site time required from surveyors and engineering personnel.

According to the manufacturer technical documentation, the steel roof structure of the tunnel is permitted to undergo a maximum vertical settlement of up to 30 mm. In contrast, the reinforced concrete structure is designed, in accordance with the project specifications, to experience a maximum horizontal displacement not exceeding 10 mm.

The deformations recorded in this study represent changes in the distance between the two opposing walls of the tunnel. Consequently, the maximum measured deformation corresponds to the combined displacement of both walls. In order to determine the individual contribution of each wall to the observed deformation, independent reference points would be required. Such reference points should be established on stable surfaces that are not mechanically connected to the monitored structure, for example, separately installed reinforcement-bar benchmarks driven into the surrounding ground or other stable reference objects located in the vicinity of the tunnel.

In the present case, the installation of independent reference points was not considered necessary, as the total measured deformation remained within the permissible design limits.

During the backfilling process, gradual changes in the measured distances were observed, indicating deformation of the structure under the increasing load imposed by the surrounding soil. The maximum change in distance recorded during the monitoring period was 8 mm, corresponding to compression of the

structure under soil pressure. This value was consistent with the design calculations and did not raise structural safety concerns. The maximum deformation was registered at the moment when the backfill height reached the transition zone between the concrete structure and the corrugated steel roof. This location is marked in red in Figure 5.

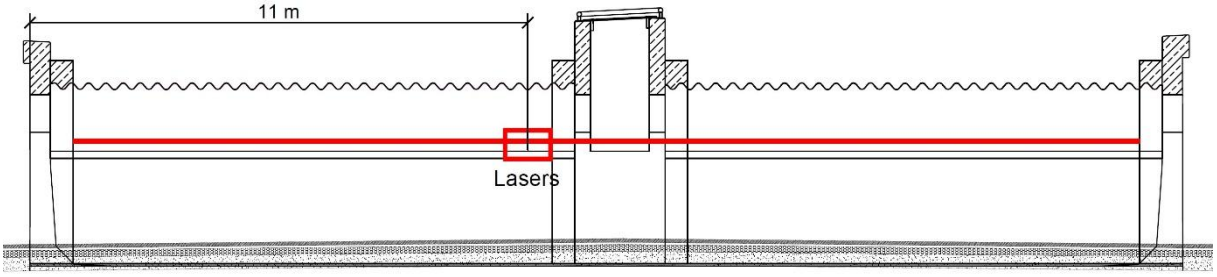


Figure 6 presents the time-dependent variation of the measured distances. The results demonstrate that deformation increased progressively with both the height of the backfill and the elapsed time since the beginning of backfilling works. The two curves also indicate different deformation rates at measurement points RP1 and RP2. Their comparison reflects the sequential nature of the backfilling process, with the deformation peak occurring first on the RP2 side.

As the laser rangefinders were not installed perpendicular to the tunnel walls and were not positioned with high-precision alignment, a discrepancy exists between the absolute distance measurements obtained from the two instruments. This discrepancy is not considered significant for the purposes of the present study, and a higher level of installation accuracy was not required.

The monitoring approach is based on the analysis of relative changes in the measurements rather than on the absolute distance values. Consequently, the deformation assessment relies on the difference between the initial baseline measurement and subsequent measurements recorded by the same laser rangefinder at the same location throughout the monitoring period.

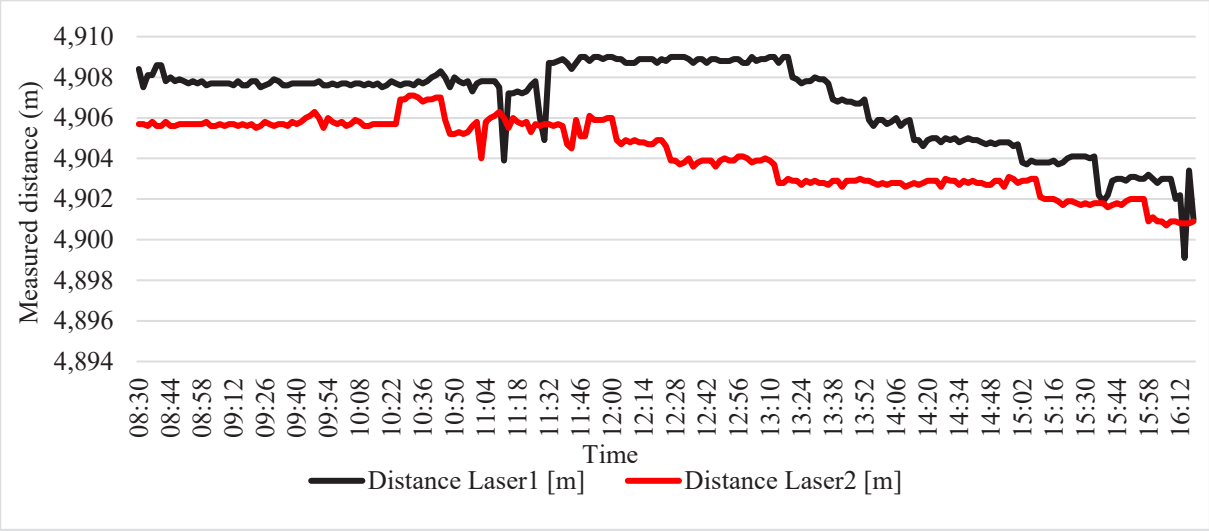
Figure 5

The soil level (red line) at which the maximum deformation was reached

A comparison of the measured results with the calculated values specified in the design documentation showed that the maximum recorded deformation of 8 mm remained within the permissible limits. This confirms the adequacy of the selected backfilling procedure and the sufficient structural stiffness of the tunnel system.

The graph in Figure 6 clearly illustrates the deformation behaviour of the structure during the backfilling process. Noticeable fluctuations are observed in the range of measurements 60–97, which are most likely associated with temperature-induced effects within the structure. The laser distance meters were activated prior to the commencement of construction works, at approximately 09:00, and therefore the influence of solar radiation during sunrise may have contributed to additional thermal deformations during the monitoring period. Such effects are considered normal and, in this case, further demonstrate the sensitivity and reliability of the applied deformation monitoring method.

Furthermore, a comparison of the two trends obtained from the separate distance meters allows identification of the sequence of backfilling on different sides of the tunnel. Although this observation is not critical for structural assessment, it provides additional insight into the structural response and behaviour during construction. This represents a further advantage of the applied monitoring approach, enhancing its informational value for practical engineering applications.



Given the relatively low cost of such devices, they can be deployed in large numbers across the monitored structure, enabling the acquisition of dense measurement data (Yang & Xu, 2021). This allows the reconstruction of a three-dimensional model of the structural behaviour under the influence of external dynamic factors during the construction process.

Despite the practical effectiveness of the proposed method, the use of laser distance meters in construction monitoring is subject to several limitations (Ma et al., 2023). The method requires an unobstructed line of sight between the instrument and the monitored point, is sensitive to changes in the position of the mounting system, and may be influenced by external factors, including vibrations and variations in ambient temperature. Under conditions typical of an active construction site, this necessitates maintaining instrument stability and carefully interpreting of short-term fluctuations in the recorded data. Such fluctuations are not always attributable solely to actual structural deformations and may instead result from external disturbances, for example when a person passes through and temporarily interrupts the laser beam during measurement.

The practical value of the proposed approach lies in its applicability not only to tunnel monitoring, but also to other infrastructure facilities that are sensitive to

deformation during construction. A similar monitoring scheme may be employed in the construction of bridges, retaining walls, and other engineering structures where prompt detection of geometric changes and control of structural response to external actions are required. In this context, the use of simple laser measurement devices may be considered a cost-effective solution for local construction monitoring, particularly in cases where the application of more complex systems is not justified.

Figure 6
Changes in the distance between tunnel walls

Conclusions

1. The application of the LBTU method during tunnel backfilling demonstrated its potential as a practical tool for monitoring geometric changes in structures during construction activities.
2. The measurement accuracy specified by the manufacturer (±1.5 mm) was sufficient to identify deformation trends and relative changes in the monitored structure during the observation period.
3. Due to its accessibility, low cost, and ease of deployment, the LBTU method may be applied at various stages of infrastructure construction projects requiring operational deformation monitoring.
4. The use of wireless laser distance meters enables the development of automated monitoring systems. Further software improvements allowing the integration of multiple sensors into a single data acquisition platform could increase the applicability of the method for larger monitoring networks (Ma et al., 2023).
5. The maximum tunnel convergence recorded during the backfilling process was 8 mm, which remained below the maximum permissible deformation limit of 10 mm specified for the reinforced concrete section of the structure.
6. The recorded measurements indicate that the method is capable of detecting not only deformation associated with construction loading but also short-term variations that may be related to thermal effects within the structure.

STRATEGIC IMPLEMENTATION OF CIRCULAR MODULAR CONSTRUCTION IN INDIAN REAL ESTATE DEVELOPMENT

***Soniya Mohankumar, Janis Zvirgzdins**
Riga Technical University, Latvia
*Corresponding author's email: Soniya.Mohankumar@rtu.lv

Abstract
The construction industry is a major user of natural resources and a significant generator of construction and demolition (CDW) waste, particularly in fast-growing, urbanizing economies such as India. The linear approach to construction leads to excessive resource use and a larger environmental footprint. Circular modular construction (CMC) combines off-site modular production with on-site assembly, incorporating circular economy principles such as design for disassembly, material reusability, and lifecycle resource efficiency. Adoption of CMC in India's real estate sector remains constrained by supply chain fragmentation, high upfront capital investment, skilled labour shortages, and regulatory uncertainties. This study develops a context-specific strategic framework that embeds circular economy principles within India's regulatory, cultural, and supply chain realities. A mixed-methods approach combines semi-structured expert interviews and qualitative case studies with a quantitative survey of 100 construction and real estate professionals, validated through an India-specific project simulation modelling CMC adoption under varying conditions. The framework covers strategic alignment, supply chain integration, technological readiness, lifecycle management, and enabling governance and digital systems. Key findings identify high capital costs and supply chain constraints as primary barriers, while organization's with greater technological readiness demonstrate stronger implementation capacity. The proposed framework shows that CMC can significantly improve project efficiency, reduce lifecycle costs, and enhance environmental sustainability in India's construction sector.
Keywords: circular economy, circular modular construction, India, real estate development, sustainability.

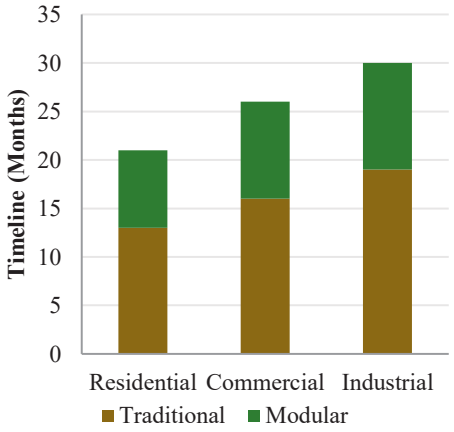
Introduction

India has been experiencing rapid urbanization and infrastructure development, resulting in significant strain on the built environment. The pressure on residential and commercial real estate development continues to mount. The construction industry plays a vital role in the national economy by creating jobs and investing in capital (Lalawmpuii & Paul, 2024). This growth has exacerbated environmental issues such as increased greenhouse gas (GHG) emissions, construction and demolition waste, and inefficient use of materials (Construction Times India, 2025; Weerakoon et al., 2025a), highlighting the urgent need for sustainable building practices. The circular economy (CE) has emerged as a transformative paradigm for improving sustainability in the construction sector. Its principles emphasize resource efficiency, long material cycles, waste reduction, and regenerative design (Movaffaghi & Yitmen, 2023). Features of circular approaches in construction include design for disassembly, modular standardization, material traceability, and reverse logistics frameworks that support reuse of building components throughout their lifecycle (Jayawardana et al., 2023; Ding et al., 2023). Modular construction offers a practical method to apply CE principles, enabling prefabrication of standardized elements off-site in controlled factory environments and assembling them on-site. This approach improves quality, shortens project durations, and reduces waste materials (Ghannad et al., 2020). Empirical evidence suggests that modular construction is more productive and environmentally friendly compared to traditional methods (Jayawardana et al., 2023). The integration of CE principles within modular construction in Indian real estate remains underdeveloped despite its numerous benefits. Obstacles include discontinuous supply chains, a lack of technical skills, financial risks, and regulatory uncertainties (Zvirgzdins et al., 2025). Existing literature primarily treats CE strategies and modular construction as separate domains, offering limited insight into their potential combination for effective operation in emerging economies such as India. In addition to technological and material innovations, decision support tools play an increasingly important role in advancing sustainable construction practices (Weerakoon et al., 2025b). The complexity of construction projects requires stakeholders to evaluate multiple criteria simultaneously, including economic feasibility, environmental performance, resource efficiency, and project risks. Decision support systems and analytical frameworks enable planners, developers, and policymakers to systematically analyse these competing factors and identify optimal strategies for sustainable development (Senaratna & Šliogerienė, 2025). Such tools are particularly valuable in emerging approaches like circular modular construction, where decisions regarding design strategies, supply chain integration, material lifecycle management, and policy alignment must be assessed holistically to ensure effective implementation and long-term sustainability outcomes.

To address the identified research gap, this study investigates the factors contributing to the success of circular modular construction in the Indian real estate industry. The study identifies key drivers and inhibitors, explores how CE principles can be incorporated into modular systems, and proposes a strategic framework to promote broader adoption. A mixed-method approach comprising expert interviews, industry surveys, case studies, and project-based analysis was employed to develop actionable strategies to advance circular modular construction in India.

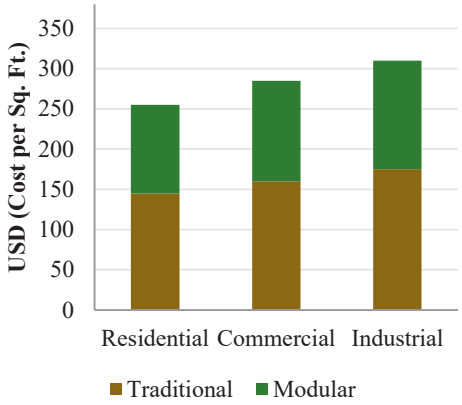
This study is guided by the following research

questions: (RQ1) What are the main drivers and barriers affecting the adoption of circular modular construction (CMC) in India's real estate sector? (RQ2) How can principles of the circular economy be effectively integrated into modular construction systems within the Indian context? (RQ3) What components of a strategic framework are necessary to facilitate scalable and sustainable CMC implementation? Based on these questions, the following hypotheses are proposed: (H1) Supply chain constraints and high initial capital requirements are the main barriers to CMC adoption in India; (H2) Organisations with higher levels of technological readiness and governance support are more likely to successfully implement CMC; (H3) A structured strategic framework that includes lifecycle management, digital systems, and regulatory alignment will significantly improve CMC adoption outcomes. The scope of this study is limited to the Indian real estate development sector and draws on empirical evidence from construction professionals, expert interviews, and project-based case analyses. The rest of this paper is structured as follows. The Literature Review section examines the relevant scientific literature. Research Methodology section outlines the methodological approach adopted in this study. Results and Discussion section presents and interprets the findings. The Conclusions section highlights main outcomes of this study, offers recommendations and suggests directions for future research.



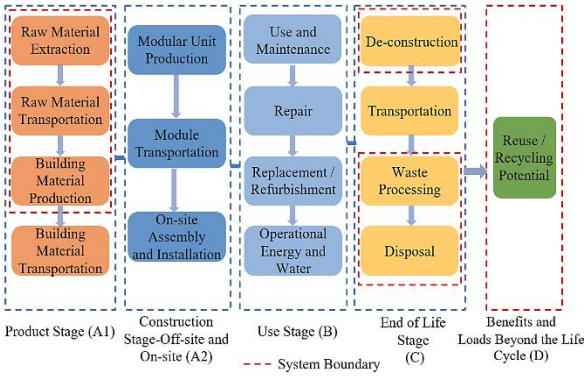
The concept of the CE has become essential for addressing issues such as resource depletion, environmental damage, and construction waste in the built environment (Zvirgzdins et al., 2019). Its foundational principles focus on efficient resource use, material reuse and recycling, and the preservation of life cycle values, from building disassembly and material traceability to reverse logistics throughout the life cycle of buildings (Movaffaghi & Yitmen, 2023). Implementing CE principles can significantly reduce embodied carbon emissions and construction waste while improving resource efficiency (Jayawardana et al., 2023). Circular waste reduction frameworks are available, such as the 3R and 6R models, with the 6R model adding refuse, rethink, and replace to the 3R model. Adopting these into mainstream construction, can offer a strong opportunity to align industry operations with national sustainability targets (Alotaibi et al., 2024). The shift from linear towards circular approaches in construction needs to be systemic and involves coordinated efforts across industry stakeholders, policy, and regulation (Ding et al., 2023). Policy instruments have become key enablers for bringing circular principles into national construction standards, including extended producer responsibility, green public procurement, and material passports (Dziedzic et al., 2024). These circular strategies are shown in the hierarchy in Figure 1 (Dung & Hong, 2021).

Figure 1
6Rs of Circular Economy (developed by the authors, based on Dung & Hong, 2021)



The modular construction method is more productive, offers better quality control and ensures schedule reliability compared to traditional construction methods (Ghannad et al., 2020). Figure 2 illustrates the reduction in project duration due to modular construction (Gómez & Sánchez, 2024).

Figure 2
Timeline Comparison between Modular and Traditional Construction (developed by the authors, based on Gómez & Sánchez, 2024)

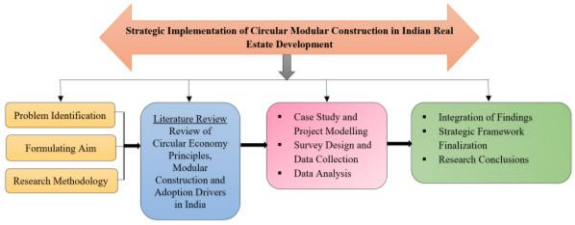


The integrated adoption of circular economy principles with modular construction remains limited across India's real estate sector (Dewagoda et al., 2024). Modular construction as a standalone approach is increasingly common in India's affordable housing and institutional infrastructure sectors. Supported by government initiatives such as the Smart Cities Mission and Pradhan Mantri Avas Yojana, its growth is driven by its scale (Lalawmpuii & Paul, 2024; Grand View Research, 2023). These economic advantages, including improved cost predictability, are shown in Figure 3 (Gómez & Sánchez 2024).

Figure 3
Cost Comparison between Modular and Traditional Construction (developed by the authors, based on Gómez & Sánchez, 2024)

Modular construction presents significant economic, environmental, and social benefits. Factory-based manufacturing minimizes workplace hazards, provides stable jobs, and supports local communities (Ferdous et al., 2019; Arif et al., 2012). Additionally, predictable schedules reduce community disturbance, and strict quality standards improve occupant comfort. In a circular economy context, these advantages are further enhanced since modules can be reused through multiple life cycles, as shown in Figure 4 (Jayawardana et al., 2023).

Figure 4
Circular Economy Framework Applied to Modular Construction (developed by the authors, based on Jayawardana et al., 2023)



Building on the theoretical foundations of circular modular construction and a critical synthesis of the current drivers, barriers, and contextual realities within the Indian construction sector, this study outlines the research methodology employed to empirically examine and verify these dynamics.

Materials and Methods

This study utilizes a mixed-method research approach to investigate how circular modular construction is strategically implemented in India's real estate sector. The research follows a sequential design, where qualitative insights inform the subsequent quantitative analysis. This method enables an in depth comprehending the multifaceted factors driving, hindering and shaping the strategic adoption of circular modular construction. In the qualitative phase, the study includes case studies and semi-structured interviews with industry experts to gain specific perspectives. The quantitative phase then employs a structured survey to validate and extend the qualitative findings across a larger professional audience. Combining these methods strengthens the rigour and relevance of the results within India's dynamic market context. Figure 5 presents the overall study framework and the methodological steps followed.

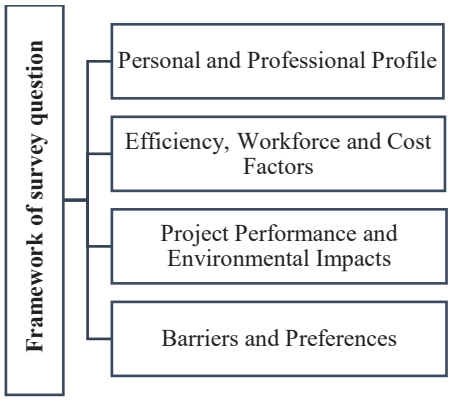


Figure 5
Circular Economy Framework Applied to Modular Construction (developed by the authors)

Initially, a systematic literature review was conducted to establish the theoretical framework underpinning the adoption of circular modular construction, focusing on strategic, organisational, and technological factors. The qualitative component included a case study of a residential duplex (20 ft. × 30 ft.), a scale deliberately chosen for three main reasons. Small-scale residential units are the most common building type in India's rapidly growing urban real estate market, making the findings broadly applicable. A limited footprint allows for precise control over key variables such as material quantities, assembly sequences, and lifecycle cost metrics, thereby improving methodological rigour. This dimension aligns with common modular grid setups frequently employed in prefabrication studies, enabling straightforward comparison between conventional and circular modular construction on a small scale within the real estate industry. AutoCAD and Autodesk 3ds Max were utilised for architectural layout and 3D visualisation, while Microsoft Project was used to model the construction schedule, resource allocation, and costs. Ten industry experts, including civil engineers, project managers, architects, contractors, and quantity surveyors, were interviewed using semi-structured methods, covering four themes: current construction practices, perceived benefits, implementation challenges, and the strategic importance of adoption. The interview transcripts were thematically analysed to identify recurring patterns. Insights gained from this qualitative phase informed the development of a structured questionnaire, which was subsequently distributed to construction and real

estate professionals to gather 100 valid responses, as shown in Figure 6.

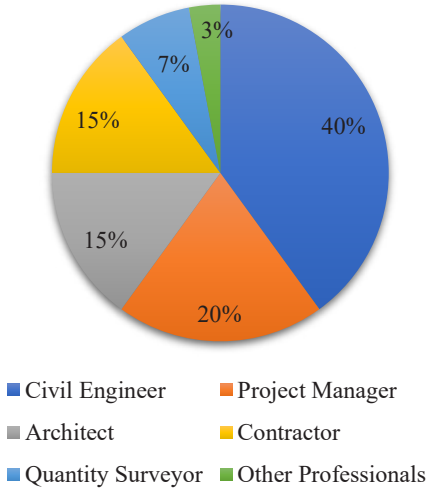
Figure 6
Framework of Survey Question (developed by the authors)

The questionnaire consisted of four thematic sections, carefully designed to capture construction professionals' perceptions of circular modular construction, as shown in Figure 6. Questions Q1 and Q2 gathered data on respondents' occupational positions and years of professional experience within Section 1. Section 2 explored efficiency, workforce, and cost considerations, specifically perceived time efficiency, on-site labour requirements, and sensitivity to cost compared to traditional construction, covering questions Q3-Q5. Section 3 assessed project performance and environmental impact, including how frequently projects are delayed, the complexity of on-site coordination, material production, quality consistency, and whether circular modular construction is linked to environmental sustainability, addressing questions Q6-Q10. Section 4 examined barriers to adoption and preferences in construction methods through two questions, Q11 and Q12; however, these were not included in the reliability analysis due to their nominal response options. Internal consistency was evaluated using Cronbach's alpha, which was determined with the Formula 1:

$$\alpha = (k/k-1)\,(1 - \Sigma S_i^2/S^{t2}) \qquad (1)$$

where k represents the number of items,
S_i^2 denotes the variance of each individual item,
S^{t2} is the total variance of the composite score.
This calculation was carried out using IBM SPSS Statistics (version 27).

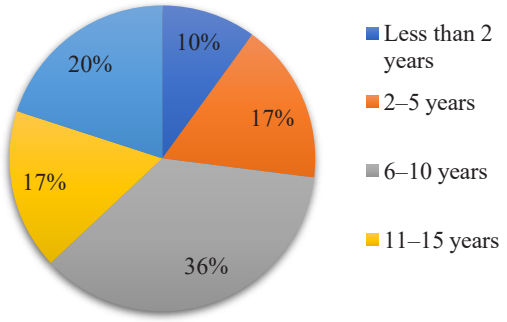
Results and Discussion



The following findings assess the feasibility, challenges, and professional perceptions of implementing circular modular construction. The internal consistency of the survey questionnaire was examined using Cronbach's alpha, which yielded a coefficient of α = 0.8884, indicating high reliability in accordance with George & Mallery (2003). Table 1 presents the descriptive statistics and item-total reliability coefficients for all ordinal scale items, which are measured on a five-point scale, with higher scores reflecting more positive perceptions of circular modular construction compared to traditional methods.

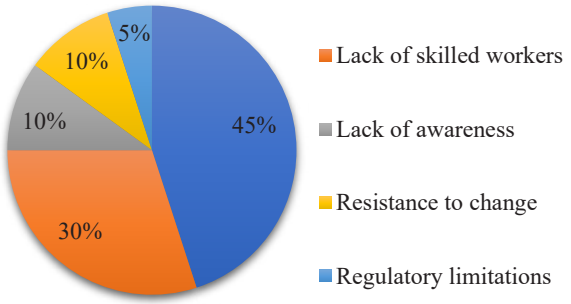
Table 1
Comparative Descriptive Statistics and Item–Total Reliability Analysis of the Questionnaire Items (N = 100) (developed by the authors, based on the IBM SPSS Statistics)

Item	Mean	SD	r	α
Q1	3.56	1.27	0.491	0.887
Q2	3.37	1.44	0.505	0.887
Q3	4.21	1.08	0.862	0.863
Q4	3.91	1.36	0.854	0.860
Q5	4.09	0.99	0.750	0.872
Q6	3.98	1.20	0.318	0.897
Q7	3.99	1.12	0.445	0.889
Q8	3.86	1.47	0.835	0.860
Q9	3.85	1.46	0.875	0.857
Q10	4.03	1.11	0.379	0.893
Overall Scale (Q1–Q10)				α=0.8884



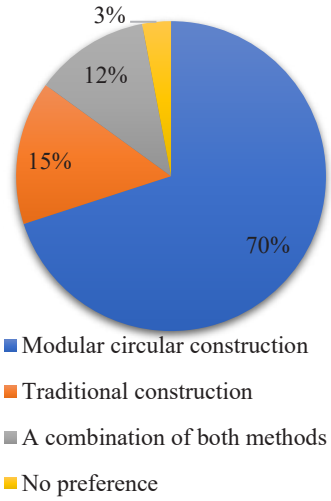
The corrected item-total correlations shown in Table 1, all surpass the minimum acceptable level of r = 0.30, indicating that every item plays a significant role in the overall construct and should not be removed from the scale. The overall Cronbach's Alpha coefficient of 0.8884 demonstrates strong internal consistency among the ten items of the ordinal scale, confirming the reliability and suitability of the questionnaire for measuring the perception of construction professionals regarding circular modular construction in the Indian real estate industry. The credibility of the findings will be with the respondents. Figure 7 shows that 40% of respondents are civil engineers, 20% are project managers, 15% are architects and contractors, and 7% are quantity surveyors.

Figure 7
Professional Background of Survey Respondents (developed by the authors)



A significant number of participants had extensive professional experience, reinforcing the validity of the survey results. As illustrated in Figure 8, the participant group spanned a range of experience levels within the construction industry. A key segment included those with vast industry expertise, indicating their strong familiarity with construction practices and project management. Other participants were at different career stages, showcasing diverse professional backgrounds.

Figure 8
Distribution of Respondents by Years of Professional Experience (developed by the authors)



Previous studies indicate that off-site production improves coordination and reduces construction time by enabling parallel workflows and controlled manufacturing conditions (Ferdous et al., 2019). Figure 7 shows that most respondents believe modular construction is faster than traditional construction methods. The resource efficiency theory also highlights that production environments under factory control reduce waste and enhance process consistency. The innovation adoption theory points out that early stages of innovation introduction are associated with economic and organizational obstacles in new technologies used in construction. According to Figure 9, the respondents list high initial investment as the greatest challenge facing modular construction, followed by a lack of skilled labour.

Figure 9
Key Barriers Identified for the Adoption of Circular Modular Construction (developed by the authors)

The diffusion of innovations theory suggests that new technologies are gradually embraced as stakeholders recognize their relative benefits (Rogers, 2003). Figure 10 supports this trend, showing that 70% of practitioners are likely to adopt circular modular construction. The remaining 15%, who prefer traditional methods, probably reflect familiarity with established workflows, concerns about capital costs, and limited awareness, highlighting the importance of targeted education and policy incentives (Dziedzic et al., 2024).

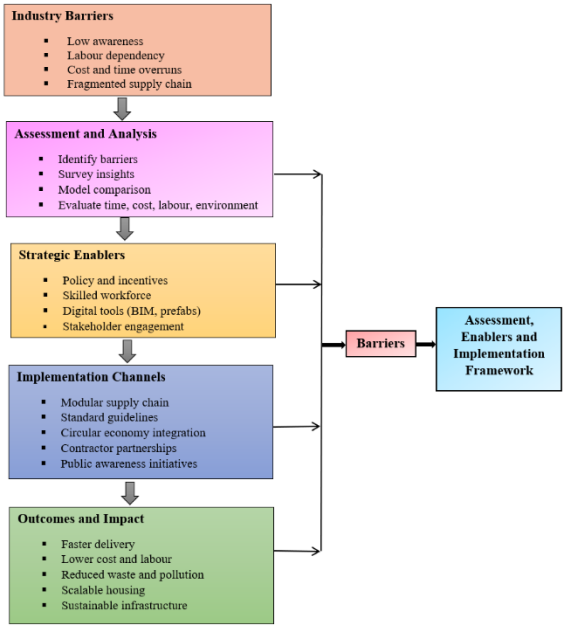
Figure 10
Preferred Construction Method among Industry Professionals (developed by the authors)

The performance disparities shown in Table 2 are explained by the scheduling simulation. Traditional construction follows a strictly linear workflow, where each phase starts only after the previous one is finished, which limits efficiency and lengthens delivery times. In contrast, circular modular construction allows for concurrent processes, with offsite module manufacturing happening at the same time as on-site foundation work. This method reduces complexity, improves resource use, and cuts waste. These efficiencies lead to noticeable reductions in project duration and cost, confirming the operational and economic viability of circular modular construction.

Conventional construction involves many operations performed sequentially on site, which can lead to labour and time inefficiencies, and project delays. In contrast, modular construction shifts a considerable portion of production to controlled factory environments, where components are manufactured in a standardized, labour-intensive approach, which boosts labour productivity, enhances material management, and reduces construction waste. To analyze these operational differences, a case study of a 20 x 30 ft. duplex residential unit was conducted. Although the project size is modest compared to large-scale developments, the case study provides a

simplified and controlled model for examining construction workflows, scheduling logic, and resource allocation patterns.

Table 2



Comparative Analysis of Traditional and Circular Modular Construction (developed by the authors, based on the MS Project results)

Metrics	Traditional Construction	Circular Modular Construction
Total Project Duration	212 days	201 days
Total Project Cost	Rs. 6.09 million	Rs. 5.07 million
Construction Phase Duration	135+ days (sequential)	90 days (parallel)
Waste Generation	High (on-site construction)	Minimal (factory controlled)
Performance Outcome	Circular modular construction reduced project duration by 5.2% and achieved a total cost saving of approximately 16.7% due to parallel workflow efficiency	

The reason for summarizing the overall project results obtained during project execution is that traditional and circular modular construction processes differ in operation while keeping the modelling complexity manageable. The key construction processes, time dependencies, and resource allocation principles illustrated in this case reflect common practices and can offer insights applicable to larger developments. Using Microsoft Project, the scheduling simulation was developed by specifying construction activities, their durations, the necessary labour, and cost parameters for both methods. This approach enabled a systematic comparison of project cost-efficiency and environmental sustainability. In traditional construction, activities are represented as sequential operations, with each task starting only after its predecessor was finished. Conversely, the circular modular scenario adopts parallel workflows, allowing off-site module fabrication to occur simultaneously with on-site foundation and infrastructure preparations. These modelling assumptions enabled a systematic comparison of project duration, labour utilization, and cost performance between the two construction techniques. The strategic implementation framework for circular modular construction within the Indian real estate sector, as shown in Figure 11, is based on the findings of this analysis. This framework identifies the main industry barriers and combines them with survey analysis and project evaluations. It also highlights strategic enablers, such as policy support, workforce development, digital technologies, and stakeholder collaboration, as key facilitators (Fan & Wu, 2020). Ultimately, the framework demonstrates how these elements can support successful adoption, thereby improving project efficiency, cost management, and environmental sustainability in India's construction industry.

Figure 11

Strategic framework for the implementation of circular modular construction in the Indian real estate sector (developed by the authors).

This proposal's framework is designed specifically for the Indian real estate sector, targeting major challenges such as fragmented supply chains, limited skilled labour, high startup costs, and insufficient regulations for circular modular construction. While grounded in the widely accepted principles of the circular economy and modular building, it is tailored to India's unique context. The framework also provides valuable insights that other developing countries facing similar urbanization and sustainability issues can adopt.

The study's findings addressed the three research questions. RQ1, which focused on the primary drivers and obstacles to CMC adoption in India, was explored through expert interviews and an industry survey. Results revealed that significant initial capital demands and fragmented supply chains are the main obstacles. RQ2, which examined the incorporation of circular economy principles into modular construction systems, was explored through a case study and literature review, highlighting practical methods for disassembly, material reuse, and lifecycle management. RQ3, which dealt with the elements of a strategic framework, was addressed through the proposed implementation framework shown in Figure 11.

H1 was confirmed, with supply chain limitations and high capital demands as the main obstacles. H2 was confirmed, as organizations with higher technological readiness showed a greater inclination to adopt CMC. H3 was confirmed, as the structured strategic

framework, which includes lifecycle management, digital systems, and regulatory alignment, demonstrated measurable improvements in project efficiency and cost outcomes.

Conclusions

1. This study assessed the feasibility of circular modular construction as a way to enhance efficiency and sustainability in the real estate sector, thereby confirming its strategic viability as a practical alternative to traditional construction methods.
2. The analysis of the Microsoft Project scheduling simulation demonstrated that the combined execution of off-site fabrication and on-site construction operations yields measurable benefits in scheduling efficiency and notably shorten the overall project duration compared to the traditional, sequential construction process.
3. Factory-controlled standardisation has been shown to improve construction quality, ensure uniform performance of materials, significantly lessen on-site waste, and support circular economy principles throughout the entire lifecycle of the built environment.
4. A structured industry survey of construction and real estate professionals indicated that the advantages of circular modular construction regarding operational, environmental, and delivery reliability are broadly recognised by construction professionals. This reflects a positive level of industry awareness and a growing willingness to adopt circular modular practices more broadly.
5. The adoption of circular modular construction in the property sector faces significant challenges due to high initial capital costs, fragmented supply chain systems, shortages of skilled workers, and regulatory uncertainties. These factors together serve as the main obstacles to its wider implementation.
6. To overcome these barriers specifically, capital cost constraints, supply chain fragmentation, skilled labour shortages and regulatory uncertainties, coordinated and sustained industry engagement is essential, supported by enabling policy frameworks, systematic workforce development programmes, and the strategic deployment of digital technologies.
7. Based on the Microsoft Project scheduling simulation and structured industry survey findings, this study offers a strategic implementation framework that links identified industry challenges to practical enabling mechanisms, providing valuable guidance for policymakers, developers, and stakeholders.
8. Future research should explore the scalability of circular modular construction across various Indian real estate typologies, examine long-term lifecycle costs, and investigate the role of emerging digital technologies such as Building Information Modelling in promoting its wider adoption.

IMPACT OF VOC EMISSIONS FROM RECYCLED BUILDING MATERIALS ON INDOOR ENVIRONMENTAL QUALITY

***Andris Stankevics, Sandra Gusta**
Latvia University of Life Sciences and Technologies, Latvia
*Corresponding author's email: andris.stankevics@lbtu.lv

Abstract
Volatile organic compounds (VOCs) emitted from construction materials are a major factor affecting indoor environmental quality and human health. As circular economy principles are increasingly adopted in the construction sector, recycled materials are being used more widely; however, their emission behavior remains insufficiently understood. This study evaluates how mechanical recycling processes affect VOC emissions from selected interior building materials, including wood-based, polymer-based, and mineral materials. A dataset reflecting realistic emission ranges reported in previous studies was used to compare total VOC (TVOC) concentrations before and after recycling. Mechanical recycling was represented by shredding, thermal exposure, and reprocessing steps, and one-way ANOVA was used to assess differences between initial and recycled materials. The results indicate that recycling may either increase or decrease VOC emissions, depending on material composition and processing conditions. The largest increases were observed for particleboard and laminate, whereas gypsum boards showed a decrease. These findings emphasize the need to integrate emission assessment into circular material design, product certification, and indoor air quality management so that environmental sustainability goals do not compromise healthy indoor environments. These findings highlight the critical importance of systematically evaluating VOC emissions throughout the entire lifecycle of construction materials, particularly when recycled content is introduced. Furthermore, they underline the necessity for developing standardized assessment frameworks that account for emission variability associated with recycling processes. Ensuring that circular economy strategies remain aligned with indoor environmental quality objectives is essential for achieving truly sustainable and health-conscious building practices.
Keywords: VOC, indoor pollutants, recycled composites, circular construction, sustainable indoor environment.

Introduction

Indoor air quality (IAQ) has become a critical concern in modern buildings, especially because improved airtightness and reduced ventilation rates in energy-efficient construction can intensify the accumulation of indoor pollutants (Wolkoff, 2013; World Health Organization, 2010). Among pollutants affecting IAQ, volatile organic compounds (VOCs) are particularly important due to their widespread presence and their potential adverse effects on comfort and health (Jones, 1999).

Building materials are a primary source of VOC emissions, especially in newly constructed or renovated indoor environments (Brown, 2002; Guo et al., 2003). Materials such as particleboard, paints, adhesives, and insulation products may release a broad range of organic compounds, including formaldehyde, benzene, and toluene (Salthammer et al., 2010). Previous research has shown that VOC emissions depend on material composition, manufacturing processes, environmental conditions, and ageing (Brown, 2002; ISO 16000-6, 2011; Yu & Crump, 2011). Wood-based materials such as particleboard and medium-density fiberboard (MDF) are known to emit formaldehyde and other aldehydes due to resin decomposition (Kim S. & Kim H. J., 2006), while polymer-based materials may release hydrocarbons, plasticizers, and degradation products (Yu & Crump, 2011).

At the same time, the construction sector is transitioning towards circular economy principles, which promote material reuse and recycling to reduce environmental impact (European Commission, 2020). Although this transition offers clear sustainability benefits, it also introduces new challenges. Recent studies on circular construction have emphasized the environmental advantages of recycling, yet the chemical implications of recycling processes remain less explored. Some authors suggest that recycling may reduce emissions because prior off-gassing has already occurred, whereas others indicate that mechanical and thermal processes may alter material structure and release previously bound VOCs (Nazaroff & Weschler, 2004; Salthammer, 2013). This inconsistency reveals an important knowledge gap regarding the emission behavior of recycled materials intended for indoor use.

Recent studies have increasingly focused on the relationship between circular construction practices and indoor environmental quality. Several authors have reported that recycled and low-carbon building materials may exhibit altered VOC emission behaviour depending on material composition, recycling technology, and ageing processes. In particular, recycled polymer-based and composite materials have been identified as potential sources of secondary VOC emissions in indoor environments (Huang et al., 2021; Li et al., 2023).

However, despite these recent advances, most published studies primarily focus on experimentally measured VOC emissions from either new or recycled building materials. Comparative assessment of emission changes associated with mechanical recycling processes using representative emission datasets remains limited. Therefore, the present study addresses this research gap by comparatively analysing representative TVOC emission ranges reported in previous studies to evaluate potential changes in VOC emissions following mechanical recycling.

This study aimed to evaluate how mechanical recycling processes influence VOC emissions from

selected building materials and to assess the potential implications for indoor environmental quality.

In addition, it is important to consider that human exposure to VOCs is not limited to individual compounds but rather to complex mixtures that may produce synergistic or cumulative health effects. Even low concentrations of multiple VOCs can contribute to sensory irritation, reduced cognitive performance, and long-term health risks. Therefore, evaluating total VOC (TVOC) levels alongside individual compound behavior is essential when assessing indoor environmental quality.

Furthermore, increasing attention is being paid to the life-cycle perspective of building materials (Kumar et al., 2021). While recycling reduces raw material consumption and waste generation, it may introduce unintended environmental trade-offs, particularly in terms of chemical emissions. The integration of indoor air quality considerations into circular economy strategies remains insufficiently developed, highlighting the need for interdisciplinary research that combines material science, environmental engineering, and public health perspectives.

Materials and Methods

The study included commonly used interior building materials: particleboard, medium-density fiberboard (MDF), laminate flooring, polyurethane insulation, painted gypsum boards, and PVC flooring.

Due to the exploratory nature of this study, representative TVOC emission values for selected building materials were comparatively analysed using emission ranges commonly reported in previous experimental studies (Brown, 2002; ISO 16000-6, 2011; ISO 16000-9, 2006; Yu & Crump, 2011). The dataset was compiled using representative TVOC emission values derived from previous experimental studies and was designed to reflect the variability commonly observed for comparable building materials under indoor conditions. Mechanical recycling conditions included shredding, thermal exposure, and material reprocessing, reflecting commonly applied recycling practices in the construction sector. These processes were considered in the comparative evaluation of VOC emission behaviour before and after recycling. The comparative analysis considered these recycling stages as the principal factors influencing changes in VOC emission behaviour between the initial and recycled material conditions. For each material group, ten representative TVOC values were used to characterise emission variability before and after recycling. One-way ANOVA was applied to assess differences between initial and recycled materials.

In addition to the selected materials, environmental parameters such as temperature and ventilation conditions were considered during interpretation of emission behaviour, as these factors are known to influence VOC emission rates. The analysis reflects emission behaviour under indoor conditions commonly described in previous experimental studies. Statistical analysis was complemented by descriptive evaluation of emission variability and changes in average TVOC levels after recycling, enabling a more comprehensive interpretation of material-specific behaviour following recycling processes.

Results and Discussion

The results demonstrated significant variation in VOC emissions depending on material type and recycling conditions. As shown in Table 1, particleboard exhibited the highest increase in TVOC emissions (+37.8%), while gypsum boards showed a reduction (−15.4%). Polymer-based materials, such as PVC, also demonstrated increased emissions after recycling.

Another relevant aspect is the potential influence of recycling-induced chemical transformations. Mechanical processing, combined with thermal exposure, may alter the chemical structure of materials, leading to the formation of new volatile compounds. These secondary emissions are not always well characterized but may contribute significantly to overall indoor pollutant loads.

From a practical perspective, the findings indicate that material selection in sustainable construction should not be based solely on environmental indicators such as recyclability or carbon footprint. Instead, a more holistic approach is required, incorporating emission performance as a key criterion. This is particularly relevant for materials used in enclosed or poorly ventilated spaces, where pollutant accumulation is more likely.

Moreover, the results underline the importance of standardized testing protocols for recycled materials. Current emission standards are primarily developed for new products, and their applicability to recycled materials remains limited. Expanding certification schemes to include recycled products would support the safer implementation of circular economy principles in the construction sector.

Figure 1 compares TVOC concentrations before and after recycling and includes standard deviations, enabling assessment of both emission magnitude and variability. The observed changes demonstrate that the effect of mechanical recycling differs among material types, indicating that VOC emission behaviour is strongly dependent on material composition and processing characteristics.

This divergence implies that the response to recycling is governed by differences in chemical composition and bonding mechanisms within the material matrix. Materials containing organic binders or additives appear more susceptible to emission increases, while mineral-based materials demonstrate comparatively stable or reduced emission profiles.

The increase in emissions from wood-based materials can be interpreted because of matrix disruption and enhanced mass transfer processes. Mechanical

fragmentation increases surface area, while thermal exposure may weaken chemical bonds within resin systems, facilitating the release of previously retained volatile compounds (Salthammer, 2013). This indicates that recycling not only reprocesses materials physically but also alters their emission kinetics.

These findings are consistent with recent studies investigating recycled composite and polymer-containing materials, which reported that mechanical processing and thermal treatment may increase VOC emissions and emission variability (Li et al., 2023).

Table 1

TVOC emissions from initial and recycled materials

Material	Initial	Recycled	Change, %
Particleboard	450	620	37.8
MDF	520	480	-7.7
Laminate	300	410	36.7
Insulation	270	350	29.6
Gypsum	390	330	-15.4
PVC	610	720	18.0

Figure 1

TVOC comparison before and after recycling

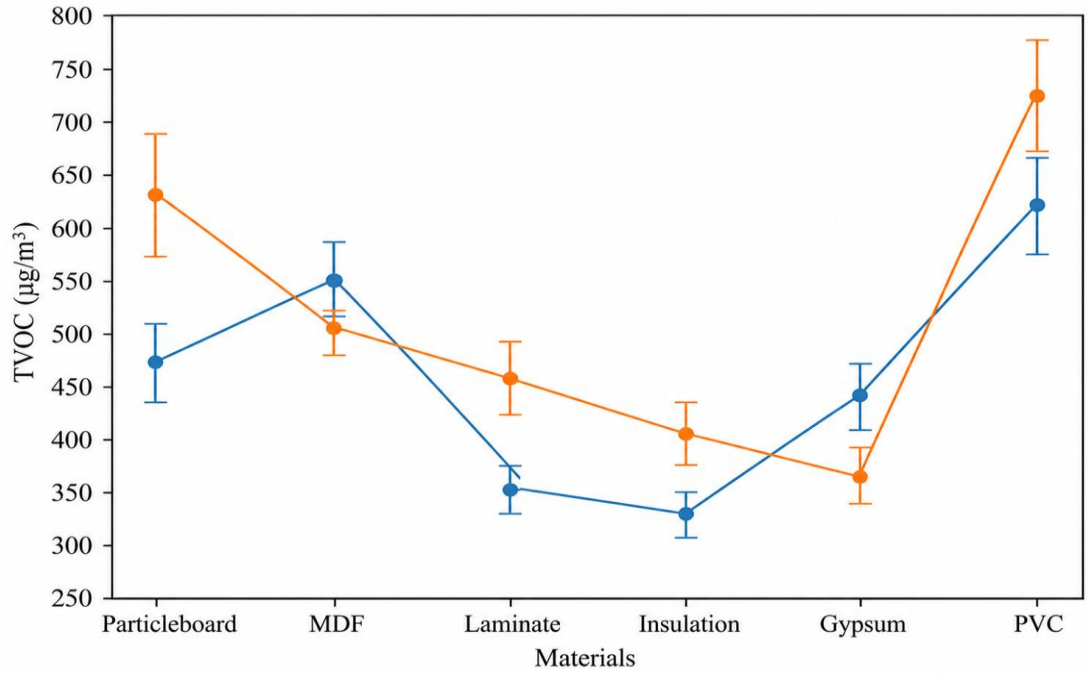

Figure 2 illustrates the percentage change in mean TVOC emissions after mechanical recycling, allowing comparison of the relative emission response among the investigated materials. The variability in percentage change reinforces that emission response is non-linear and cannot be generalized across material categories. Instead, it reflects the interaction between initial material properties and recycling conditions. Figure 3 illustrates the distribution of TVOC emissions before and after mechanical recycling, highlighting the increased variability observed for particleboard and PVC compared with the other investigated materials. This suggests that recycling introduces heterogeneity into the material structure, leading to less predictable emission behavior. From an indoor air quality perspective, such variability is critical, as it increases uncertainty in exposure assessment and complicates the application of standard emission limits. Therefore, evaluating recycled materials based solely on mean TVOC values may be insufficient, and greater emphasis should be placed on variability and material-specific response patterns when assessing their suitability for indoor use.

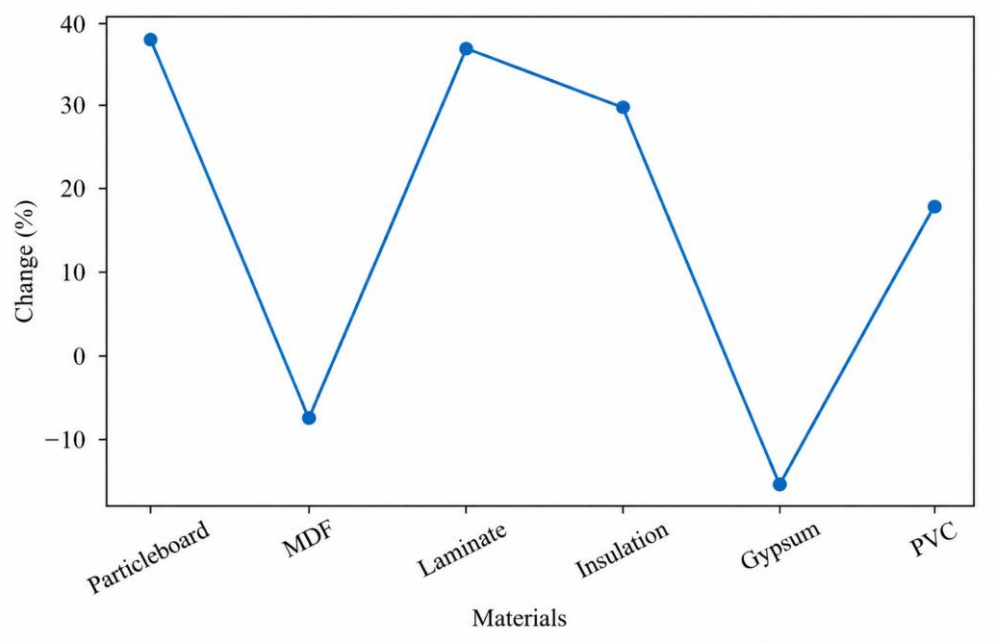
In contrast, reduced emissions in gypsum materials may be related to prior off-gassing and lower organic compound content (Brown, 2002).

Figure 2
Percentage change in mean TVOC emissions after mechanical recycling



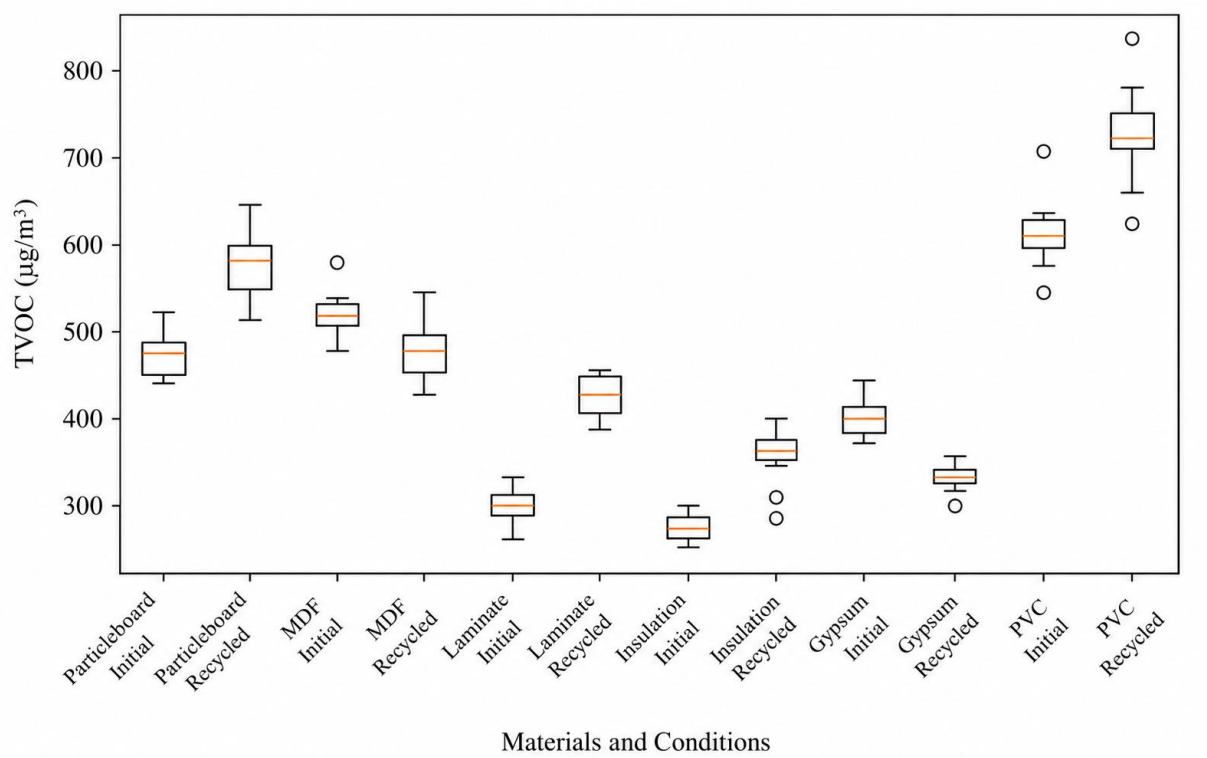


Figure 3
Distribution of TVOC emissions for initial and recycled materials based on measurements (n = 10)

One-way ANOVA revealed statistically significant differences in VOC emissions between initial and recycled materials ($F(1, 58) \approx 5.2–9.8$, $p < 0.05$), indicating that recycling processes significantly influence emission characteristics. These results confirm that the observed changes are not random but are systematically associated with the recycling process itself. The statistical significance further supports the assumption that mechanical and thermal treatment steps measurably alter emission behavior. From an environmental and engineering perspective, these findings highlight a critical trade-off in circular construction. While recycling improves resource efficiency and reduces environmental burdens associated with raw material extraction, it may negatively affect indoor air quality if emission behavior is not properly assessed (Hellweg & Milà i Canals, 2014). This trade-off underscores the need for

a more balanced evaluation framework that considers both environmental sustainability and human health impacts.

Therefore, VOC emissions should be systematically integrated into material certification systems, circular design strategies, and indoor air quality regulations. Current assessment frameworks often prioritize energy performance and material reuse, while emission-related aspects remain secondary. Incorporating emission criteria into these systems would enable more informed decision-making and reduce potential risks associated with recycled materials.

Although the present analysis reflects representative emission trends reported in previous studies, further laboratory-based validation remains necessary. Experimental studies under controlled conditions would help to confirm the observed patterns, reduce uncertainty, and support the development of standardized testing methods specifically tailored for recycled building materials.

Future Research Directions

Despite the results obtained in this study, several aspects of VOC emissions from recycled building materials require further investigation to ensure their safe and sustainable use in indoor environments. The findings provide important indications of changes in emission behaviour due to recycling; however, they do not fully represent the complexity of real-world emission dynamics under actual operating conditions. Therefore, future research should prioritize experimental validation under controlled laboratory conditions using emission test chambers in accordance with established international standards such as ISO 16000-9.

One important direction for future research is the assessment of long-term emission behavior. VOC emissions from building materials are known to change over time due to ageing processes, material degradation, and environmental influences. While this study focuses on initial emission changes after recycling, it does not address how emissions evolve during extended periods of indoor use.

In addition, further research should focus on the identification and quantification of individual VOC compounds rather than relying solely on total VOC (TVOC) values. Although TVOC is a useful indicator of overall emission intensity, it does not reflect the specific health risks associated with compounds, such as formaldehyde, benzene, or other hazardous substances.

Another critical area for investigation is the influence of different recycling technologies on emission behavior. This study considers mechanical recycling processes, including shredding and thermal exposure; however, other recycling methods, such as chemical recycling or hybrid processes, may produce different emission outcomes.

Furthermore, the interaction between recycled materials and indoor environmental conditions should be explored in greater detail. Factors such as temperature, humidity, ventilation rate, and the presence of reactive pollutants (e.g., ozone) can significantly affect emission rates and secondary pollutant formation.

The increased variability in emissions observed in this study also highlights the need for improved standardization and quality control of recycled materials. Future work should investigate the sources of this variability, including differences in feedstock composition, processing conditions, and material heterogeneity. Developing more consistent recycling practices and classification systems for recycled materials could reduce uncertainty and improve the predictability of emission performance.

Finally, there is a need to integrate VOC emission considerations into life cycle assessment (LCA) and circular economy frameworks. While recycling offers clear environmental benefits in terms of resource efficiency and waste reduction, its potential impact on indoor air quality is often overlooked. Future interdisciplinary research combining material science, environmental engineering, and public health perspectives would support the development of more comprehensive evaluation tools that balance sustainability and human health**.**

Conclusions

1. Recycling processes significantly influence VOC emission behavior in building materials. The results of this study indicate that mechanical recycling, including shredding and thermal exposure, can measurably and systematically alter emission characteristics.

2. Both increases and decreases in emissions were observed, depending on material composition and processing conditions. This indicates that recycling does not produce a uniform effect but rather acts as a modifying factor influenced by the material's chemical and structural properties.

3. Wood-based and polymer materials tended to show increased emissions after recycling, whereas gypsum boards showed lower emissions. The observed increase in emissions from wood-based materials can be associated with the degradation of resin systems and increased surface area, while the relatively stable behavior of mineral-based materials reflects their lower organic compound content.

4. In addition to changes in average emission levels, recycling was associated with increased variability in VOC emissions. This suggests that recycled materials may exhibit less predictable emission behavior, which can complicate indoor air quality assessment and risk management in real-world building environments.

5. The findings of this study support the integration of VOC emission assessment into circular construction strategies and material certification systems. Current sustainability frameworks often prioritize resource efficiency and waste reduction, but this study's findings highlight the need to also consider potential impacts on indoor environmental quality and human health.

6. From a practical perspective, the selection of building materials for indoor use should not rely solely on environmental indicators such as recyclability or carbon footprint. Instead, a more comprehensive approach is required, with emission performance as a key decision-making criterion, particularly in low-ventilation or energy-efficient buildings.
7. Future research should focus on laboratory validation, long-term emission studies, and standardized testing methods for recycled materials, as well as on identifying specific VOCs and their health implications.
Overall, this study highlights the complex relationship between material recycling and indoor environmental quality. While recycling is essential for sustainable resource management and supports the transition towards a circular economy, its impact on VOC emissions cannot be overlooked. The results demonstrate that emission behavior is highly material-dependent and influenced by processing conditions, emphasizing the importance of integrating emission considerations into material design, certification, and building practices. A balanced approach is therefore required to ensure that environmental sustainability goals are achieved without compromising healthy indoor environments.

SUSTAINABLE DEVELOPMENT DRIVERS IN THE LATVIAN CONSTRUCTION INDUSTRY

Inese Biuksane
Research Institute for Business and Social Processes, Latvia
Corresponding author's e-mail: inese.biuksane@inbox.lv

Abstract
Nowadays, the impact of globalization on the world economy has contributed to the expansion of international markets and increased competition, labor mobility and the associated knowledge flow, the need for innovation and the introduction of technological processes. In the last decade, increased attention within the European Union has been devoted to promoting environmentally friendly construction, energy efficiency and reduction of greenhouse gas emission reductions, to facilitate the implementation of the European Green Deal and the transition to a sustainable and climate-neutral environment. The construction industry is one of the most important driving forces of the national economy, significantly influencing not only the country's economic growth, but also the environmental sustainability and the quality of life for society. The development of the construction industry is proceeding differently in different countries, and this raises a discussion about the causes of these differences and the sensitivity of the industry. The aim of the research is to analyse the development of the Latvian construction industry and identify the key drivers contributing to the sustainable growth of the industry. The Latvian construction sector is a labour-intensive industry that is primarily driven by domestic market demand and public investment. Growing sustainability requirements, rapid technological advancements, and workforce availability challenges highlight the need to enhance the sector's development potential through investments in human capital and market expansion. Fostering growth will boost national economic performance and help achieve the European Union's broader objectives.
Keywords: construction, innovations, growth, technologies.

Introduction

The construction industry is one of the most important driving forces of the national economy, significantly influencing not only the country's economic growth, but also environmental sustainability and society's quality of life (European Parliament, 2023). In the European Union, the construction industry is strictly regulated, with a particular emphasis on ensuring quality, safety and sustainability, while promoting digitalization, innovation and the implementation of circular economy principles (European Parliament, 2024b). Over the past decade, in the European Union has devoted increasing attention to promoting environmentally friendly construction, energy efficiency, and the reduction of greenhouse gas emissions (European Parliament, 2023) to facilitate the implementation of the European Green Deal and the transition to a sustainable, climate-neutral environment (European Parliament, 2024a).

In recent years, the development of the construction industry in the European Union and the Baltic States has been significantly affected by Russia's war in Ukraine. After the war started, in 2022, the construction industry faced significant disruptions in the supply of building materials, price increases, and rise in the cost of energy resources, which significantly affected the costs and planning of construction work. Meanwhile, there was an increase in the demand for defence and security infrastructure, construction and reconstruction of strategic buildings, as well as expansion of the housing stock. Although the upheavals caused by the war initially hindered the growth of the construction industry, in the long term they served as a powerful stimulus for change, encouraging the Baltic States to purposefully move towards energy independence, strengthening security, and reinforcing the principles of sustainable development in the field of construction.

Research aim – to analyse the development of the Latvian construction industry and identify the key drivers contributing to the sustainable growth of the industry. To reach the aim, the following tasks were put forward: 1) to select indicators for assessing the development of the construction industry; 2) to analyze the development trends of the construction industry in the Baltic States; 3) to identify the drivers determining the sustainable growth of the Latvian construction industry.

Several methods and software tools were used in the development of the research.

Materials and Methods

The European Union and the Latvian construction industry is an industry of the national economy consisting of 4 sub-industries – construction of buildings, civil engineering, specialised construction activities – which belong to the secondary economic sector, and architectural and engineering activities technical testing and analysis, which are a part of the tertiary economic sector (Central Statistical Bureau, 2025a). Sub-industries consist of several sectors and their sub-sectors, which differ in their type of activity and have different development potential.

The socio-economic indicators used in this study were selected based on widely recognized approaches in the scientific literature for assessing industry competitiveness, development, and economic impact. The number of enterprises (Bakri, 2021) characterizes business activity and market structure within the industry. The number of employed persons (Solvell et al., 2003; Shah, 2024) and the educational attainment of employees (OECD, 2025) reflect the availability and quality of human capital, which are important determinants of industry competitiveness and

productivity. Labour costs (Musarat et al., 2022) and labour productivity (Porter, 1990) describe the efficiency of resource utilization and business competitiveness. Gross value added (Liu et al., 2021) reflects the industry's contribution to the national economy, while export value (Abdmoulah, 2023) indicates international competitiveness and the industry's ability to generate value in external markets. The shadow economy index (Buszko, 2020) was selected as an indicator for assessing the impact of informal economic activity on industry development, whereas foreign direct investment (Irandoust, 2016) reflects the industry's attractiveness to investors and its development potential. The scientific literature was used as a theoretical basis for the selection of the indicators included in the study and for substantiating their relevance to the analysis of the construction industry's development.

The study employs general scientific, statistical, and mathematical research methods. The theoretical part of the research is based on the analysis of scientific literature, legal and regulatory acts, policy planning documents, and other information sources in order to identify the factors influencing the development of the construction industry, evaluate aspects of industry competitiveness, and justify the selection of the indicators used in the study. Statistical research methods, including data collection and grouping, comparative analysis, structural analysis, and time-series analysis, were applied to characterize the phenomenon under investigation and identify its development trends. Mathematical methods (including correlation analysis) were used for quantitative data analysis, the identification of relationships between variables, and the assessment of development trends. Analysis and synthesis methods were employed for the formulation of conclusions and recommendations. Microsoft Excel was used for data processing, analysis, and visualization of the research results.

The analysis covers the period from 2011 – 2023. For certain reporting years, data are not available or cannot be published due to lack of information and confidentiality. The availability and quality of the data determined the level of details and the results.

Results and Discussion

Development of the Construction Industry in the Baltic States

The construction industry in the Baltic States has become an important segment of economics in recent decades, reflecting both the dynamics of the region's development and trends in sustainable architecture and technological innovation. At the same time, the industry faces several challenges that require a thoughtful approach and interdisciplinary cooperation to ensure sustainable development.

Labour costs in the Baltic States are considerably lower than in the EU on average, but with a tendency to increase (Figure 1a). The cheap labour in the Baltic States may choose work with equivalent working conditions in another industry or abroad, but for a much more competitive work remuneration, which can thus create increasingly greater fluctuations in labour flows and affect the construction capacities of companies.

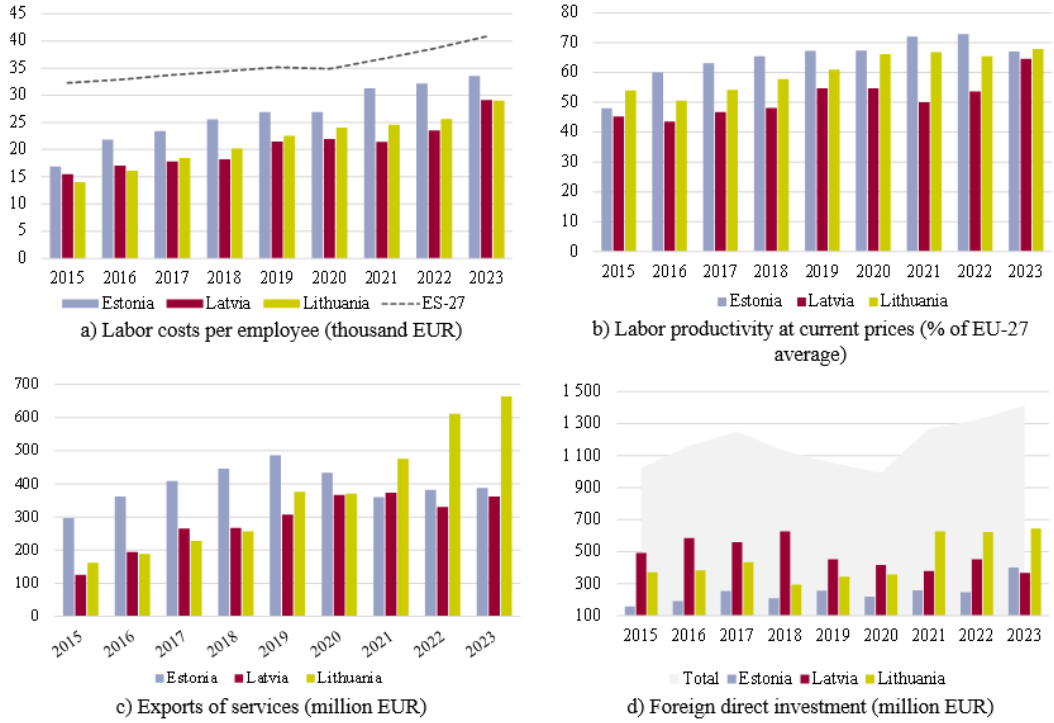
Labour productivity in the Baltic States falls significantly behind the average in the EU (Figure 1b). Moreover, the labour costs in all the Baltic States grow faster than productivity. An increase in labour costs that is not matched by a proportional rise in productivity may diminish the profits of companies in the construction industry, thereby hindering their capacity to invest in their further development.

Over the past 10 years, the exports of the Baltic States have quadrupled, reaching 1.41 billion euros in 2023 (Figure 1c). Until 2020, Estonia was the export leader among the Baltic States, but since 2021 it is Lithuania. The increase in the proportion of construction industry exports in relation to the gross domestic product points to the growth of the industry in the Baltic States and indicates the increasing competitiveness of the services of the industry's companies in international markets.

An average of 1.18 billion EUR is invested annually in the development of the construction industry in the Baltic States (Figure 1d). Investments in Latvia's construction industry have long exceeded those in Lithuania and Estonia, driven by an active investment attraction policy, favorable real estate development conditions, increasing urbanization, and the absorption of EU funds that enabled ambitious infrastructure projects. Over the past 3 years, the Lithuanian construction industry has become more attractive to foreign investors.

The development of the construction industry in the Baltic States is hampered by the slow transformation to knowledge-intensive activities – the use of low-skilled labour, slow adoption of modern technologies and lack of mechanisation, underutilised digitalization potential, as well as the weak integration of industry companies into global value chains. The growth of the industry is also hindered by insufficient investment in research and development, as well as a lack of cooperation with scientific institutions in creating innovations.

Development of construction industry in Latvia



In 2023, there were 13,17 thousand economically active companies in the Latvian construction industry, the vast majority of which (87%) were micro-enterprises (Figure 2a). Construction companies employed more than 70 thousand employees, or 8% of the total number of persons employed in the country (Figure 2b). The construction industry can be described as a labour-intensive industry – it held the position of the 7th largest employer among all the industries of the national economy in Latvia.

The gross value added of the construction industry in 2023 reached 2.44 billion EUR, accounting for nearly 7% of the total value added of the Latvian economy (Figure 2b). Fluctuations in the share of the industry's

value added in the overall national economy of the country are mainly related to the more rapid development of other industries of the national economy. The construction industry is highly correlated with the overall economic situation in the country – it develops cyclically alongside the broader economy, serving as a direct mirror of the economic growth.

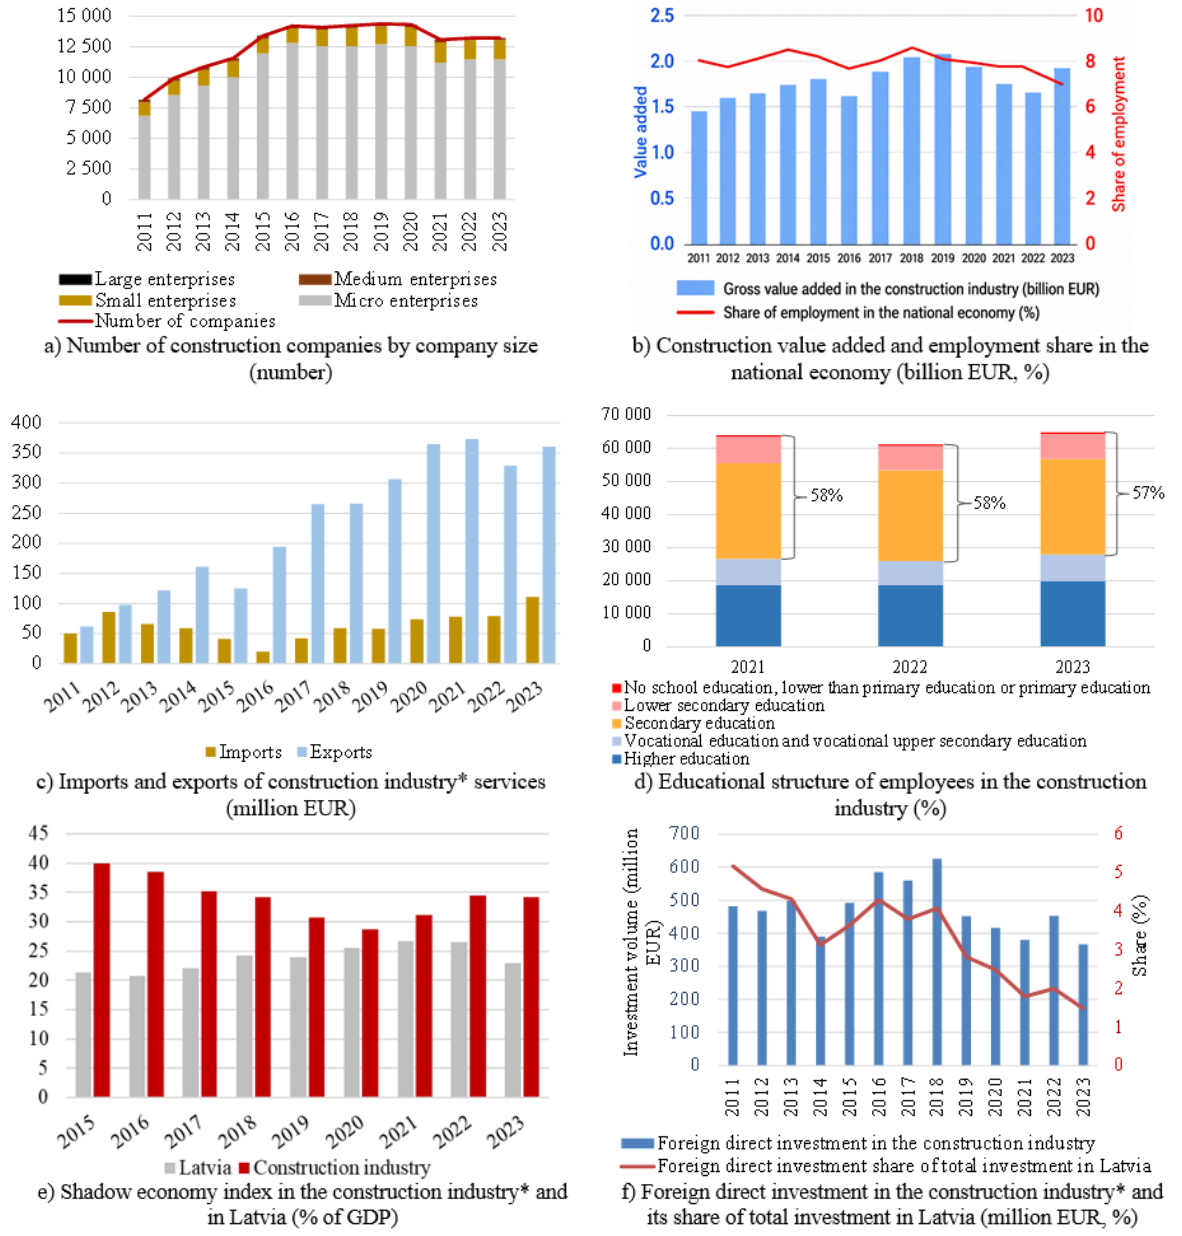
Figure 1

The structure of the construction industry in the EU-27 and Latvia (created by the author according to Eurostat, 2026)

Note: The available data on the construction industry, excluding architectural and engineering activities, technical testing and analysis.

The internal consumption of construction works in the domestic market has increased by 85% since 2015, reaching 3.23 billion EUR in 2023 (Central Statistical Bureau, 2026b). The highest consumption was observed in construction of buildings, which can be explained by the inflow of the EU funds and financial instruments into the Latvian national economy, leading to a growing demand for government-ordered buildings, office buildings, and residential houses. Construction consumption also increased in specialised construction activities and civil engineering. Companies operating in the Latvian construction industry mainly serve the local market; therefore, the industry is closely linked to total investments in the national economy and is highly dependent on public procurement. The industry is poorly oriented towards entering export markets, even though exports have tripled over the past ten years (Figure 2c).

The construction industry has a large impact not only on the labour market, but also on migration. Insufficient demand for construction work reduces the industry's need for labour, causing some of those who have lost their jobs to reorient themselves toward equivalent work in another industry or emigrate to other countries. In turn, under conditions of rapid economic growth and high demand for construction work, the industry may create a disproportionately high demand for labour and compete for workers with other industries. From the perspective of balanced economic growth, it is important to ensure that the construction industry develops without rapid declines and increases.



Activity of the Latvian construction industry is based primarily on low-skilled (Figure 2d) and therefore low-cost labour, rather than on technological advancement and innovations. The average monthly gross work remuneration of workers in the construction industry (excluding architectural and engineering activities, technical testing and analysis) in 2023 was EUR 1449 a month (Central Statistical Bureau, 2026b), which was 6% less than the average work remuneration in the Latvian national economy. Employees in the specialised construction, building construction, and micro and small industrial enterprises earned less than the average remuneration in the construction industry and Latvia overall.

The proportion of the persons employed who receives the minimum wage or less has decreased from 37% in 2011 to 16% in 2023. Although the average gross work

remuneration in the construction industry has increased twice since 2011, which was significantly influenced by the concluded General Agreement, it is still not competitive in either the local or the EU labour market. Due to the uncompetitive remuneration and high working environment risks in construction the companies may face difficulties in attracting qualified labour, and these factors can contribute to the spread of envelope wages, failing to achieve the desired effect in combating the shadow economy (Figure 2e).

Figure 2

Development Indicators of the Latvian Construction Industry 2011–2023 (calculated and created by the author according to Central Statistical Bureau, 2026b; Latvia Bank, 2026; Stockholm School of Economics in Riga, 2025)

*Note: *The available data on the construction industry, excluding architectural and engineering activities, technical testing and analysis.*

Foreign direct investments in the Latvian construction industry are on a downward trend – since 2011, the volume of the investments has fallen by 24%, reaching 367 million EUR in 2023 (Figure 2f), which can be explained by instability in the global economy and the increased geopolitical risks. Investments in the construction industry are rather inconsistent and their volatility is influenced by both the availability and cyclicality of the EU funds, as well as adjustments to private sector investment plans in line with changes in the state of market. Investment inflows are also hampered by high energy costs, low lending levels, and complex construction processes.

Conclusions

1. In recent years, the construction industry in Lithuania has experienced the fastest growth among the Baltic States. This development has been driven by the implementation of large-scale infrastructure projects, high labor productivity, and an active real estate market, which has contributed to attracting significant investments. The stable growth of Lithuania's construction industry has promoted the development of an investment-friendly environment and increased the country's attractiveness to foreign investors, strengthening its competitiveness within the Baltic region.
2. Latvia's construction industry is a labor-intensive sector primarily oriented toward the domestic market and public procurement, developing cyclically in line with the country's overall economic situation. Although growth has been observed in the construction sector in recent years, the industry as a whole is still insufficiently focused on the adoption of new knowledge and technologies, as well as the implementation of innovations. The growth of Latvia's construction industry should be promoted through investments in human capital, technology transfer, and innovation development. The sector should establish close and long-term cooperation with universities and scientific institutions both nationally and internationally to foster networking, facilitate the knowledge and experience transfer, and support a shift toward higher-productivity activities. Strengthening the construction industry can contribute not only to enhancing public quality of life, but also to driving national economic growth and advancing broader European Union objectives more effectively.

*Corresponding author's email: Sivakumaranumolu95@gmail.com

Abstract
This article presents a literature study on the shear behaviour and failure of Steel Fibre-Reinforced Concrete (SFRC) beams, with a particular focus on the effects of fibre volume fraction, fibre geometry and distribution, as well as the interaction between the steel fibres and shear reinforcement. The literature study discusses the findings from numerous published experimental researches involving various fibre types and how steel fibres increase shear strength via crack bridging, shear force redistribution and improvement in post cracking behaviour. A comprehensive database collected from the literature covers the findings of a variety of shear tests performed on SFRC beams, both with and without fibres. The review analyses the effect of different key parameters including fibre volume fraction, specimen size, aspect ratio, $\frac{a}{d}$ (shear span to depth ratio) and crack width on shear strength. The review suggests that enhancing the fibre amount (up to 2%) increases shear strength and minimizes the crack width. However, higher $\frac{a}{d}$ ratios diminish shear capacity due to a fall in the arching action. The review suggest that specimen size strongly impacts shear strength, with smaller specimens revealing a higher normalized shear strength. Although there have been wide range improvements in experimental ways and techniques, shear strength models of SFRC beams have insufficient correlation with experiments' results and reveals minimal sensitivity to the mechanical properties of the fibres, fracture kinematics and size effects. These drawbacks emphasize the importance of developing more precise predictive models that incorporate the essential concepts governing shear resistance in Steel Fibre Reinforced Concrete (SFRC).
Keywords: steel fibre-reinforced concrete (SFRC), shear strength, fibre reinforcement, fibre geometry, stirrups.

Introduction

Shear Problem in RC Beams

Shear failure in reinforced concrete (RC) beams is one of the most essential structural issues owing to its brittle character, speed, and the fact that they cannot give sufficient warning before their collapse (Lantsoght, 2019; Arslan et al., 2017). Compared with flexural stiffness failure which is governed by the yielding of longitudinal reinforcement and shows great ductility, the shear failure is controlled by major principal tensile stresses with limited capacity for stress redistribution and results in unstable crack propagation and sudden failure in loss of load carrying capacity (Zhao et al., 2018).

Shear resistance in shear capacity RC beams is given by combination of concrete contribution, mixture interlock, dowel action of longitudinal reinforcement and transverse reinforcement in form of stirrups. However, experimental evidence shows that after the composite of diagonal cracks, these mechanisms lose their stability quickly, especially because of the loss of aggregate interlock, leading to extremely unstable post-cracking behaviour (Lantsoght et al., 2019). While stirrups increase the shear capacity and delay the size of crack, they do not prevent crack processes and may be inappropriate for brittle shear failure control in unfavourable geometrical and detailing restrictions in beams.

Justification on the use of Shear Steel Fibre Reinforced Concrete

Steel fibre reinforced concrete (SFRC) has been more and more studied as a mechanism-based technique for improving the shear performance by improving post-cracking load transfer. Following the formation of the diagonal crack, the steel fibres act as discrete bridging elements across the crack surfaces. This helps to transfer tensile stresses and limit crack openings, thereby controlling crack propagation (Saudi Abdul-Zaher et al., 2016; Amin & Foster, 2016).

The main role of fibres in the shear direction is not to increase the pre-cracking strength but to increase the post-cracking shear capacity transfer mechanisms.

This behaviour is especially relevant in stirrup reinforcement where shear critical applications are evolved and the spacing (stirrup reinforcement) requirements, congestion problems or construction issues limit the spacing for stirrup reinforcement. By addressing directly, the deficiency about post-cracking shear transfer, SFRC helps to offer a complementary reinforcement mechanism to make the structure more robust against brittle diagonal tension failure.

Fragmentation and Inconsistencies in Available Literature

After some research work on the shear attributes of SFRC beam, reported results show great variance because of variation in fibre type, volume fraction, $\frac{a}{d}$, and the presence or absence of stirrups (Arslan et al., 2017; Demakos et al., 2021; Zhao et al., 2018).

Moreso, loading configurations, beam dimensions, boundary conditions from different studies (Demakos et al., 2021) shows how the parameters and the crack evolution affect the shear failure and mechanism-consistent design, formulations may be developed.

Review Gap and Contribution

Existing reviews on steel fibre reinforced concrete mainly stay on the matter of material properties, flexural behaviour or overall character of the concrete with little attention on the beam scale shear mechanisms (Behbahani et al., 2011). Although various research studies on hybrid fibre systems have been conducted providing information on the subject, they are still fragmented and there is no established understanding about shear specific behaviour at the structural level (Akbulut et al., 2025).

Consequently, there is a critical gap in linking the experimental evidence, governing parameters, and the mechanistic interpretation of post-cracking shear transfer and the evolution of failure of the SFRC beams. Steel fibres are assumed as the main reinforcement mechanism because of their dominant importance in crack bridging and stress transfer while others are considered in the rest of the paper, where they are important for mechanistic understanding (de Resende & Cardoso, 2023; Zhao et al., 2018).

Both SFRC beams with and without conventional stirrups are studied in order to analyse interaction effect of fibre bridging and transverse reinforcement on controlling shear behaviour (Amin & Foster, 2016; de Resende & Cardoso, 2023).

Materials and Methods

Review type and its Position

This study provides a critical review and synthesis of experimental evidences regarding the shear behaviour and failure mechanisms in steel fibre-reinforced concrete (SFRC) beams. Unlike reviews that focus solely on material-scale properties from coupon tests, the present review examines beam-scale behaviour to ensure direct relevance to structural performance and design applications (Lantsoght et al., 2019).

Instead of focusing solely on ultimate strength prediction, the review emphasizes shear transfer principles, crack evolution, and failure modes. Consequently, this approach provides mechanistic insight into the interaction between steel fibres and concrete reinforcement under shear stress, particularly regarding post-cracking bridging and stress redistribution, which are crucial for SFRC behaviour (de Resende & Cardoso, 2023).

By grounding up the review in experimental evidence at the beam level and focusing analysis on core mechanics, this study ensures that its conclusions are technically defensible, relevant to engineering practice, and directly linked to key gaps in the literature. This approach aligns with the rigour of the database-derived and crack-bridging analyses, thereby providing a transparent and credible synthesis of the shear behaviour of SFRCs (Lantsoght et al., 2019).

Inclusion Criteria

The scope of this review was purposefully designed to ensure direct relevance to shear-critical behaviour in steel fibre-reinforced concrete (SFRC) beams. Only studies that met the following inclusion criteria were considered:

1) Experimental Studies on SFRC Beams. The present review was restricted to beam-scale experimental studies and does not include material coupon or flexure-only tests. This restriction ensures that all findings directly relate to the structural performance and mechanistic understanding of deformation and shear failure (Amin & Foster, 2016; Zhao et al., 2018).

2) Loading Configuration. The included studies reflect results from three-point or four-point bending tests, which are the standard configurations for evaluating shear-critical responses and diagonal crack formation in RC beams (Amin & Foster, 2016; Yuan et al., 2020).

3) Shear-Critical Conditions. Only beams subjected to shear-dominated stress states were included. Studies addressing flexural behaviour alone - or those focussing solely on global capacity without explicitly evaluating shear transfer mechanism - were excluded.

Both beams with and without transverse reinforcement or stirrups were included which allowed to compare the fibre contribution for various cases of shear reinforcement (i.e. with and without stirrups) (Amin & Foster, 2016; Yuan et al., 2020; Zhao et al., 2024).

By applying these strict inclusion criteria, this review employs a rigorous method that yields transparent, defensible results, ensuring all conclusions are grounded in high-quality experimental evidence on SFRC shear behaviour.

Exclusion Criteria

To maintain rigorous validation, explicit measures were taken to exclude studies where findings could not be attributed directly to shear behaviour.

The following categories were excluded from this review:

1) Purely numerical studies lacking experimental validation to verify model accuracy.

2) Material-level testing on non-beam specimens (e.g., pull-out tests, notched prisms, or small-scale coupons), unless the study established an explicit link between material-level response and beam-scale shear behaviour. This avoids over-generalising material-level properties to structural performance (Khan et al., 2022).

3) Investigations focused solely on flexural capacity, impact resistance, or durability with no specific regard for shear transfer mechanisms or failure mode development. While informative on other structural aspects, such studies do not contribute directly to the primary objective of evaluating SFRC shear behaviour (Meda et al., 2012; He et al., 2022).

These exclusions align directly with the review's scope, which emphasises beam-scale shear behaviour and failure mechanisms. This focus distinguishes the present study from broader SFRC reviews that cover general material or flexural properties (Meda et al., 2012).

Results and Discussion

Overview of the Compiled Database and General Shear Behaviour Trends

A comprehensive database was compiled from the reviewed experimental investigations, comprising of Figure 1 to Figure 6, shear-critical tests on SFRC beams both with and without stirrups. The results extracted from the compiled studies are presented in Figures 1-6, displaying total shear strength across a wide range of parameters. Key variables include fibre volume fraction (V_f ranging from 0% to approximately 3%), longitudinal reinforcement ratio (ρ_l from 0% to 3%), and shear span-to-depth ratio (a/d from approximately 0.5 to 4.5). Data points from Figure 1 and 6 differentiate between graphs with fibres

(filled circles) and without fibres (triangles), as well as beams without stirrups and with stirrups. Author-specific series are colour-coded for traceability (e.g., Zhao et al., 2018 in pink/magenta, Amin & Foster, 2016 in red).

Overall trends confirm that the addition of steel fibres consistently increases post-cracking shear capacity relative to plain reinforced concrete (RC) beams. Fibres activate immediately upon diagonal crack formation, providing crack-bridging tensile stresses that stabilise crack propagation, preserve aggregate interlock, and enable stress redistribution. This transforms the inherently brittle shear failure of conventional RC into a more ductile, gradual process, even in the absence of stirrups. The graphs further reveal synergistic effects when fibres are combined with stirrups, with enhanced post-peak load-carrying capacity and reduced crack widths. These observations align directly with the mechanistic justification presented in Section 1.2 and address the literature fragmentation noted in Section 1.3.

Effect of Fibre Volume Fraction (V_f) on Shear Stress

The influence of fibre volume fraction is one of the most pronounced parameters, as evidenced by Figures 1 and 2. Figure 1 presents normalised shear strength (τ/f_c) versus $V_f(\%)$ for beams without stirrups. A clear positive correlation is apparent in several author series, notably Zhao et al. (2018) (pink series), where stress increases from approximately 0.26 atV_f = 0% to 0.29 at $V_f \approx 2\%$. Other series (e.g., Amin & Foster, 2016 in red) show modest but consistent gains with rising V_f, while a minority exhibit flatter or slightly declining trends attributable to specific fibre geometries or workability issues at higher dosages. Critically, specimens with fibres (filled circles) generally plot above the without-fibre triangles at equivalent V_f = 0, confirming the fibre-bridging contribution. The upper-bound trend line (magenta) across the dataset rises gently up to $V_f \approx 2\%$, beyond which marginal returns diminish consistently with practical limits on workability and fibre orientation efficiency.

Figure 2 extends this analysis to beams with stirrups and reveals even stronger benefits. Multiple linear regression trends (e.g., Zhao et al., 2018 in purple) demonstrate steep positive slopes, with τ/f_c rising from ~0.15 at V_f = 0% to over 0.22 at $V_f \approx$ 2–2.5%. Demakos et al. (2021) (yellow-green) and Kevinly et al. (2025) (green) series similarly confirm upward trajectories. The synergy arises because fibres reduce tensile demands on stirrups, delay crack widening, and maintain shear transfer mechanisms longer into the post-cracking regime. Mechanistically, higher V_f increases the number of crack-bridging elements per unit crack area, enhancing direct tension and dowel-like action across inclined cracks (de Resende & Cardoso, 2023; Zhao et al., 2024). These graphs therefore substantiate the review's assertion in the abstract that fibre contents up to 2% markedly improve shear stress while minimising crack widths.

Failure Modes and Mechanisms of transitions & Their Classification of Failure Modes

SFRC beams develop three major failure modes: brittle shear failure, mixed shear-flexural failure and flexure dominated failure. Experimental studies indicate that fibres affect the stability and evolution of these modes in contrast to introducing new mechanics (Saudi Abdul-Zaher et al., 2016; Lantsoght, 2019).

Effect of Shear Span-to-Depth Ratio $\left(\frac{a}{d}\right)$ (1)

where:

a is the shear span,

d is the effective depth of the beam.

The shear span-to-depth ratio exerts a dominant influence on arching action and the transition from shear-compression to diagonal-tension failure. Figure 5 (representative of the a/d plots provided) shows a clear decreasing trend in τ/f_c with increasing a/d for beams without stirrups. At low a/d (≈1.0-1.5), stress reach 0.10 - 0.15 (e.g., Demakos et al., 2021 yellow-green and Kevinly et al., 2025 teal series), reflecting pronounced arching. As a/d rises beyond 2.0, values drop sharply to 0.03 - 0.07, with fitted trend lines (magenta and yellow) confirming the inverse relationship. Fibre-reinforced circles maintain higher residuals than without-fibre triangles at all a/d levels, demonstrating that fibres partially mitigate the loss of arching by sustaining crack-bridging stresses. Higher $\frac{a}{d}$ also correlates with wider cracks and more brittle post-peak response unless compensated by adequate V_f (Arslan et al., 2017; de Resende & Cardoso, 2023).

Initiation of Shear Crack of SFRCs Beams

Shear cracks in steel fibre reinforced concrete (SFRC) beams initiate in similar way as the conventional reinforced concrete beams, which is initiated when principal tensile stresses exceed the tensile capacity of concrete matrix (Arslan et al., 2017; Zhao et al., 2018). Available experimental evidence shows that the use of steel fibres has little effect on the diagonal cracking load, especially at low to moderate fibre volume fraction level, as fibre contribution before forming the crack is minimal (Arslan et al., 2017; Zhao et al., 2018).

Influence of Longitudinal Reinforcement Ratio (ρ_l)

Longitudinal reinforcement ratio (ρ_l) contributes to shear resistance through dowel action and confinement of the compression zone. Figure 3 illustrates τ/f_c versus ρ_l (%) for beams without stirrups. The data exhibit moderate scatter, yet a general positive trend emerges within individual author clusters. For example, Zhao et al. (2018) (pink) and Zhi et al. (2025) (magenta) points at higher ρ_l (≈2–3%) achieve τ/f_c values exceeding 0.25-0.30, while lower-ρ_l specimens (ρ_l < 1%) cluster below 0.05 - 0.10 in some series.

Without-fibre triangles (at $\rho_l \approx$ 2 - 3%) typically fall below fibre-reinforced circles, underscoring that fibres compensate for lower ρ_l by sustaining post-crack tensile capacity. The teal trend line (Meda et al., 2012) shows a modest upward slope, indicating that increased ρ_l enhances dowel action, which fibres further stabilise.

Figure 1
Normalized Shear stress ($\frac{\tau}{f_c}$) versus fibre volume fraction (V_f) for beams without stirrups

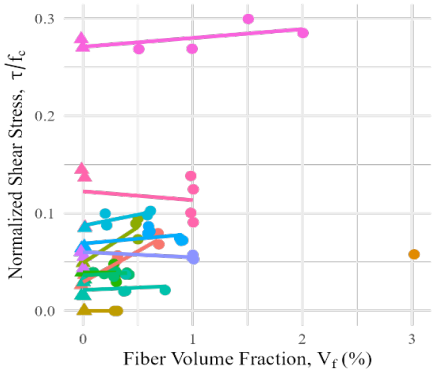

Figure 2
Normalized Shear stress ($\frac{\tau}{f_c}$) versus fibre volume fraction (V_f) for beams with stirrups

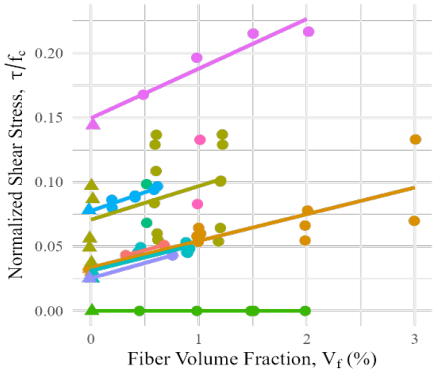

Figure 3
Normalized Shear stress ($\frac{\tau}{f_c}$) vs longitudinal reinforcement ratio (ρ_l) for beams without stirrups

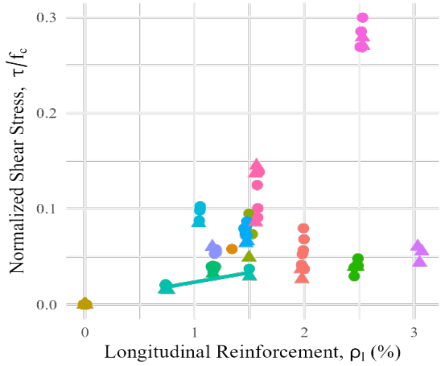

Figure 4
Normalized Shear stress ($\frac{\tau}{f_c}$) versus longitudinal reinforcement ratio (ρ_l) for beams with stirrups

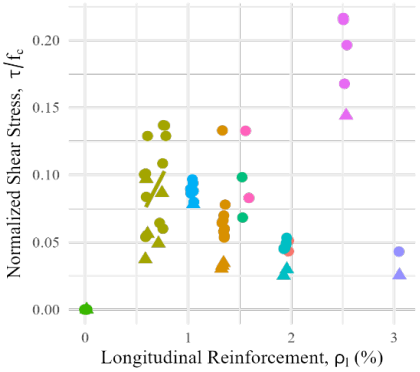

Figure 5
Influence of shear span-to-depth ratio ($\frac{a}{d}$) on shear stress ($\frac{\tau}{f_c}$) without stirrups

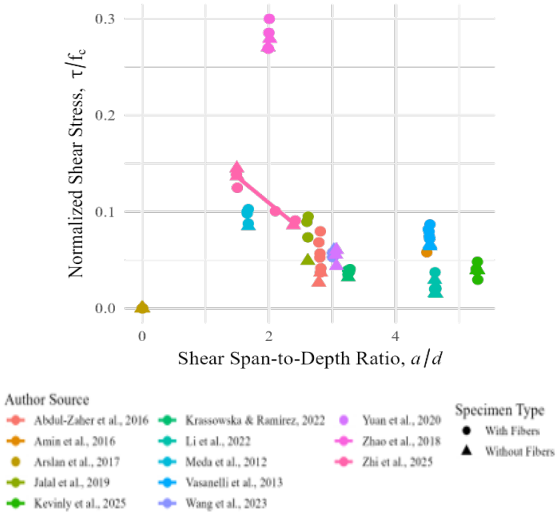

Figure 6
Influence of shear span-to-depth ratio ($\frac{a}{d}$) on shear stress ($\frac{\tau}{f_c}$) without stirrups

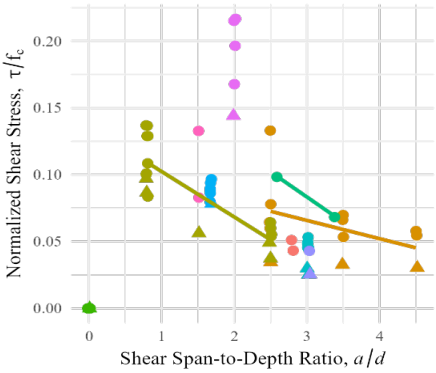

Figure 4 repeats the analysis for beams with stirrups. Here, the scatter is wider, but positive correlations are evident in Zhao et al. (2018) (purple) and Demakos et al. (2021) (yellow-green) series, where τ/f_c from ~0.05 at low ρl to over 0.20 at $\rho_l \approx 2.5$ - 3%. Without-fibre triangles again plot lower, confirming the complementary role of fibres even when stirrups are present. The interaction is mechanistic: higher ρ_l improves arching and dowel resistance, while fibres control diagonal crack opening, allowing stirrups to yield more gradually and thereby increasing overall ductility (Amin & Foster, 2016; Yuan et al., 2020).

Crack Evolution, Failure Modes, Post-Cracking Shear Transfer, and Interaction with Stirrups

Diagonal cracks initiate at loads comparable to plain RC, yet fibres engage instantaneously, limiting initial crack widths and enabling multiple secondary cracks. Post-cracking shear transfer occurs via fibre bridging (direct tension across crack faces), residual aggregate interlock, and enhanced dowel action mechanisms that remain effective even at crack openings up to several millimetres. Failure modes shift from sudden diagonal tension (plain RC) to gradual shear-compression or flexure-shear in SFRC, with fibres and stirrups together producing the most ductile response. The graphs in Figures (1-6) collectively illustrate that hybrid reinforcement yields the highest τ/f_c and smoothest post-peak behaviour, allowing reduced stirrup congestion without sacrificing capacity or robustness (Amin & Foster, 2016; Zhao et al., 2024).

Limitations and Future Research Directions

The compiled results from the illustrated Figures 1-6 indicate longitudinal reinforcement ratio and fibre volume ratio. This Figure indicates that shear resistance in SFRC beams is postulated by a fibre interaction, aggregate interlock, cracks development.

No comparison with the existing predictive models was carried out. Therefore, the data Figures models cannot be indicated from the current data.

Future research should focus on:

- Experimental measurement of crack width, crack slip, and fibre pull-out behavior.
- Large-scale beam tests to quantify size effects on shear resistance.
- Development of models that incorporate fibre efficiency through Figure 1-6 such as fibre aspect ratio ($\frac{l_f}{d_f}$), volume fraction (V_f), and bond effectiveness.

The results confirm that steel fibres contribute to post-cracking shear resistance by limiting crack widths and improving stress transfer across diagonal cracks. However, incorporating these into a design models requires further research and experimental validation.

Propagation of Crack and Post Cracking Stabilized

Following crack initiation, the propagation behaviour of diagonal cracks of SFRC beams is out of line with that in the case of conventional reinforced concrete. Depending on the beam's type, diagonal cracks usually spread quickly to the compression area causing unstable failure in beams that have no fibres. In contrast, experimental researches indicate that fibre reinforcement is responsible for reducing crack propagation rate and promoting the crack branching, which leads to a more distributed cracking pattern (de Resende & Cardoso, 2023).

Experimental results reported by Demakos et al. (2021) suggest that fibre reinforced beams have enhanced deformation capacity with controlled crack widening which can be interpreted as the post-cracking stability. This behaviour is assumed to be attributed to fibre bridging which seems to provide resistance across crack faces and thereby delays localization.

Crack Width development and Distributions

Crack width evolution is an intervening property of SFRC shear behaviour. Experimental studies have always shown that SFRC beams develop more than one and finer diagonal crack instead of single dominant crack, meaning that stress distribution among several cracking planes takes place (Arslan et al., 2017; Saudi Abdul-Zaher et al., 2016).

Direct experimental measurements by de Resende & Cardoso (2023) confirm that fibre bridging helps in delaying the localization of the crack as well as allows to sustain higher shear stresses at similar crack widths. However, such behaviour is conditional. When the fibre pull-out or rupture occurs, the crack widening starts to accelerate rapidly, and there is a lack of shear transfer capacity (Zhao et al., 2018; Zhao et al., 2024).

Effect of Shear-Span to Depth Ratio $\frac{a}{d}$

The ratio of the shear-span to depth (a/d) controls the inclination of crack and predominate load transfer mechanism. Experimental evidence indicates that low $\frac{a}{d}$ ratios lead to steep diagonal cracks and strongly shear-dominated behaviour which reduces the effectiveness of fibre bridging (Arslan et al., 2017; Demakos et al., 2021).

On the contrary, higher a/d ratios enable more gradual crack development and more interactions between fibres and crack surface to improve post-cracking shear resistance (Picazo et al., 2025). This suggests that the effectiveness of the fibre is thus geometry-dependent, and not intrinsic.

Interaction between Fibre Bridging and Stirrups

In beams where fibres and stirrups are used together, the shear resistance depends on the interaction between the member rather than independent contribution. Amin & Foster (2016) proved that the fibres are responsible for crack opening reduction and stirrup yielding, delaying them by transferring the tensile stress over diagonal cracks.

Yuan et al. (2020) further showed that fibre contribution is more significant in the early post-cracking stages while stirrups are a major factor at larger crack widths. This pushing after-pulling type of interaction shows the complementary nature of fibre and conventional shear reinforcement.

Crack localization and Onset of Failure

Despite improvements in the control of cracks, SFRC beams ultimately fail by localization of a critical diagonal. Experimental evidence shows that failure

occurs due to the fibre bridging capacity which either subdues the pull-out or rupture effect through which cracks are rapidly widened, and aggregate interlock is lost (Zhao et al., 2018, 2024).

Fibres provide delayed, and not enough, eliminating brittle shear failure, especially in deep beams or at insufficient fibre content (Saudi Abdul-Zaher et al., 2016; Demakos et al., 2021). This is a confirmation that fibre reinforcement alters the process of failure, and not the basic mechanism.

Duration of Brittle Shear Failure

Brittle shear failure is also a possibility in SFRC beams. Experimental results show that the beams with low fibre content have behaviour similar to conventional reinforced concrete with only moderate improvements in the strength (Saudi Abdul-Zaher et al., 2016).

Zhao et al. (2018) stated that fibre bridging delays the localization of the crack, but when the pull-out capacity is exceeded, it does not prevent the failure. This shows that the nature of fibre reinforcement will not change fundamentally the mechanism of shear failure.

It is observed that with a sufficient fibre volume fraction, a transition to mixed shear-flexural behaviour takes place, leading to stable crack growth and an enhanced ability to deform (de Resende & Cardoso, 2023; Saudi Abdul-Zaher et al., 2016).

Arslan et al. (2017) showed that the crack localization is delayed, i.e., the failure process is more gradual, with increasing the fibre volume fraction.

Flexure-Dominated Failure

Flexure-dominated failure can be observed when the shear resistance is sufficiently improved with the help of fibre reinforcement. This behaviour is observed in beams with higher $\frac{a}{d}$ ratios and sufficient fibre content mostly (Lantsoght, 2019; Resende & Cardoso, 2023).

Amin & Foster (2016) demonstrated that adding fibres reduces the strain demand in stirrups and postpones their yielding.

Yuan et al. (2020) demonstrated that beams with lower stirrup ratios can still achieve equivalent shear performance due to the contribution of steel fibres, thereby confirming the existence of interaction effects.

Conclusions

1. Hooked-end fibres are also associated with better anchorage and higher pull-out resistance, which leads to better crack bridging.
2. Increasing fibre content enhances shear resistance and delays crack localization. However, excessive fibre content reduces ductility and can cause fibre balling.
3. Low $\frac{a}{d}$ ratios favour shear primary behaviour which reduces effectiveness of fibres. Increased ratios increase fibre interaction; increased beam depth makes the fibre less active due to the effect of the stress mixture.
4. It shows that steel fibre primarily elevates the post cracking shear behaviour and the ductility of the reinforced concrete beams by stabilizing the dispersion of the diagonal cracks and improving the crack distribution. While fibres may postpone the localisation of the crack and favour the mixed shear-flexural mode of failure, they do not fundamentally eliminate the shear failure, particularly those in deep beams or those with low shear-span-to-depth-ratio configurations. The effectiveness of fibre is very conditional to fibre type, volume fraction, anchorage, geometry of the beam and arrangement of reinforcement with hooked-end fibre and slender beams showing maximum benefits. Experimental evidence suggest that fibres perform a complementary reinforcement instead of a complete replacement of stirrups. Current modelling approaches and design provisions are still limited in terms of including fibre bridging, size effects, and staged fibre-stirrup interaction, and there is a need for mechanism-based numerical modelling and large-scale experimental validation. Overall, steel fibres have great potential to improve shear ductility and post-cracking performance, but the contribution of steel fibres must be carefully incorporated into design and code development through geometry-aware and evidence-based approaches.

EXPERIMENTAL INVESTIGATION OF BUCKLING STABILITY OF NON-COMPOSITE-SECTION MULTI-LAYER PANELS UNDER AXIAL COMPRESSION

Abstract
This paper addresses the buckling stability of multi-layer sandwich wall panels with non-composite connections, where only one layer is subjected to axial compression, whilst adjacent layers enhance its buckling resistance despite the absence of composite action between layers. The aim is to experimentally investigate whether a non-composite connection between a loaded and an unloaded layer can enhance the buckling stability of slender structural elements, to optimise sandwich wall panel design. Small-scale physical models were used for the investigation. Critical buckling height was determined analytically using Euler's formula. Two specimen groups were tested: 300 mm high specimens corresponding to 2.2 times the critical height and 400 mm high specimens corresponding to 3 times the critical height. Each group included plain steel plates (control group) and a series of specimens strengthened with a plywood plate fixed at a distance. Compression load was applied only to the steel plate (5 × 100 mm cross-section). Lateral deflections and ultimate load capacity were measured. Results demonstrate that adjacent layers with non-composite connection improve structural stability. Specimens strengthened with the plywood plates exhibited 43% increase in load-bearing capacity for the 300 mm series and 69% increase for the 400 mm series compared with plain plates. These findings suggest that the loaded layer of sandwich wall panels with non-composite connections can exhibit higher load-bearing capacity. This has important implications for optimising lightweight sandwich panel construction, where mechanical fastening creates a similar non-composite interaction between structural and non-structural layers.
Keywords: buckling resistance, thin-walled structures, sandwich panels, non-composite action, shear connectors.

Introduction

Sandwich-type wall structures (SW) can be used as any other structural wall, with the advantage of having an insulation layer between two concrete layers (PCI Committee on Precast Sandwich Wall Panels, 2011). This configuration allows for improved quality and reduced time and cost of construction work.

To increase the effectiveness of SW, many researchers propose reducing the thickness of the layers. This can be achieved by replacing conventional steel reinforcement, which requires thick concrete cover, with other more advanced types of reinforcement (Kim & You, 2015; Lameiras et al., 2013; O'Hegarty et al., 2019; Sylaj & Fam, 2021). The thickness of the layers in thin-layer SW ranges between 20 and 75 mm (Kim & Allard, 2020; Mugahed Amran et al., 2020; Tawil et al., 2022).

Due to the slender layers, one of the main challenges is preventing the loaded layer from buckling. A strategy is to ensure composite action between the layers to increase the overall stiffness of the cross-section and, consequently, the critical load. Although composite action in SW results in structural advantages, such as flexural stiffness and increased buckling resistance, there are some shortcomings as well. First, achieving full composite action is difficult, as most shear connectors provide only partial composite behaviour (Puzanova & Skadins, 2025). Second, SW with composite action is subjected to bowing, resulting in higher stresses (Skadiņš et al., 2023; Tomlinson & Fam, 2016).

A previous numerical study suggests that even non-composite connection between the loaded and the adjacent layers can increase the load-bearing capacity of SW by postponing buckling of the loaded layer (Skadiņš et al., 2023). To the authors' knowledge, there is no systematic analysis of the buckling performance of thin-layer SW with non-composite connections. Such a configuration of SW would simplify the manufacturing process, prevent the walls from bowing due to temperature or solar radiation loading, and create combined action between the layers to increase the stability of the loaded layer.

This study presents an experimental investigation using small, slender steel plates strengthened with unloaded plywood plates. The aim is to investigate the effect of the adjacent (unloaded) layer on the buckling of a loaded, slender layer connected with non-composite connectors. The following hypothesis is proposed: a non-composite mechanical connection between a loaded slender layer and an adjacent unloaded layer can increase the buckling load compared to an unstrengthened loaded layer. To achieve and the stated aim, the following tasks were set: (1) design and fabricate small-scale test specimens representing loaded and unloaded layer configurations; (2) determine critical buckling height analytically; (3) conduct axial compression tests and measure lateral deflections and ultimate load capacity; (4) compare load-bearing capacity of plain and strengthened specimens. The obtained results can later be applied to improve design strategies for real SW panels manufactured from concrete or combined concrete and cross-laminated timber.

Materials and Methods

In this study, four series of small-size specimens (12 specimens in total) were fabricated and tested under axial compression until failure to evaluate the effect of the adjacent unloaded layer.

Specimens

The test specimens consisted of one or two elements – a slender steel plate and, in two series, a plywood plate.

The loaded layer was made of S235 grade steel, while the unloaded layer was 18 mm thick birch plywood. A total of four series were tested under axial compression: two series of plain plates (30 and 40) and two series of strengthened plates (30_18 and 40_18). Each series included three specimens with identical cross-sectional dimensions of the load-bearing steel plate element, measuring 5×100 mm. The specimen parameters of all series are summarised in Table 1. The elements were connected with M4 mm threaded rods, with horizontal spacing $s_x = 60$ mm and vertical spacing $s_{y1} = 110$ mm; in series 4 and 4_18, $s_{y2} = 120$ mm. The edge distances were $e_v = 30$ mm in the vertical direction and $e_x = 20$ mm in the horizontal direction. The clear distance between layers was $h_0 = 60$ mm, creating a non-composite gap connection between the loaded and unloaded elements, as illustrated in Figure 1.

Figure 1
Schematic representation of specimen geometry. (1 – steel plate, 2 – birch plywood layer, 3 – M4 threaded rod connector, 4 – screw nut)

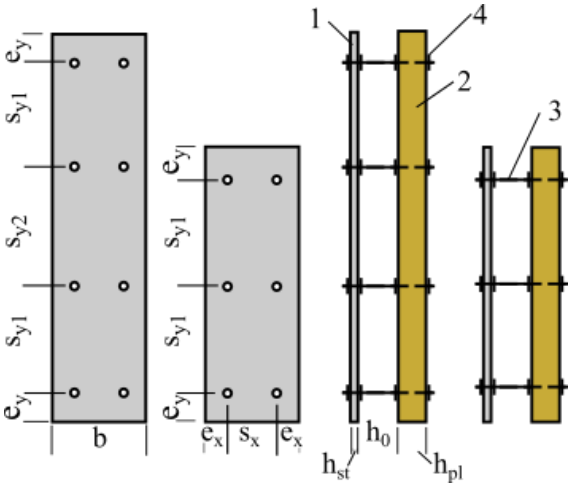

Table 1
Test specimen parameters

Series	Number of spec.	Height, mm	Strengthening element
30	3	300	–
30_18	3	300	18 mm plywood
40	3	400	–
40_18	3	400	18 mm plywood

The steel plate was selected as the primary test material due to its isotropic nature – meaning its mechanical properties are uniform in all directions – making it the most suitable material for initial experimental investigation. The steel material properties adopted in this study are assumed to be consistent with the values specified in Eurocode 3 (CEN, 2005) and summarised in Table 2. Birch plywood properties for 18 mm are adopted from Ozola (2018) and are summarised in Table 3.

The critical buckling length l_{cr} was determined using formula (3), derived from Euler's buckling equation (1), where the critical stress σ_{cr}(2) is replaced by the yield strength f_y of steel, ensuring that the specimen failure occurs due to buckling rather than material yielding.

Table 2
Mechanical properties of steel S235

Property	Symbol	Value	Unit
Modulus of elasticity	E_s	210000	MPa
Yield strength	f_y	235	MPa
Ultimate tensile strength	f_u	360	MPa

Table 3
Mechanical properties of birch plywood

Property	Symbol	Value	Unit
Modulus of elasticity	E_{pl}	10000	MPa
Bending strength	f_m	40.2	MPa
Tensile strength	f_t	39.2	MPa
Compressive strength	f_c	27.2	MPa
Shear strength	f_v	9.5	MPa
Density	ρ	680	kg/m^3

$$F_{cr} = \frac{\pi^2 \cdot E \cdot I}{l^2} \quad (1)$$

$$\sigma_{cr} = \frac{F_{cr}}{A} \quad (2)$$

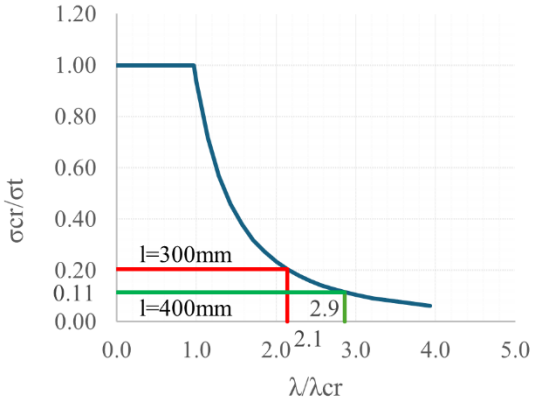
$$l_{cr} = \sqrt{\frac{\pi^2 \cdot E \cdot I}{f_y \cdot A}} \quad (3)$$

I is the second moment of area of the cross-section about the axis of least resistance, E is the modulus of elasticity of the material, l – effective length of the specimen, and A is the cross-sectional area of the loaded steel plate.

The critical buckling length l_{cr} determined according to formula (3) for a steel plate with strength class S235 and the cross section of 5×100 mm for the axis of least resistance is 135.6 mm.

The slenderness ratio of the steel plate λ, as well as the critical height determined with respect to the axis of least resistance, was calculated according to formulas (4) and (5), where i_{min} denotes the minimum radius of gyration:

$$\lambda = \frac{\mu \cdot l}{i_{min}} \quad (4)$$



$$i_{min} = \sqrt{\frac{I}{A}} \quad (5)$$

The effective length factor was taken as $\mu = 1$, corresponding to pin-ended boundary conditions. In the experimental setup, these conditions were achieved by providing appropriate supports – pinned at the bottom and roller support at the top as shown in Figure 3.

The length of the specimens (300 and 400 mm) was selected for experimental testing, corresponding to ratios of critical stress to yield stress of 0.2 and 0.11, respectively, as illustrated in Figure 2. These values were chosen to ensure that the specimens fail due to buckling rather than reaching strength criteria and to evaluate the effect of the slenderness.

Figure 2

Normalized critical stress versus normalized slenderness ratio for S235steel with a 5×100 mm cross-section

Test set-up

The specimens were loaded using a servo-hydraulic testing machine Form-Test Delta-5. The load was applied axially along the longitudinal axis of the specimen, ensuring controlled and incremental loading as illustrated in Figure 3.

Lateral deformations were measured at mid-span of the steel plate using a linear variable differential transformer (LVDT) type transducer with a measurement resolution of 1/1000 mm. Measurements were recorded continuously throughout the loading process, allowing the acquisition of complete load–deformation curves and enabling analysis of the specimen's structural behaviour.

Prior to loading, the initial geometric imperfections of all steel plates were measured using a feeler gauge (range: 0.002–1.00 mm). The measured imperfection values range from 0.1 to 0.5 mm and are summarised in Table 4.

Results and Discussion

The experimentally obtained maximum loads and corresponding statistical parameters for all four series are summarised in Table 5 and illustrated in Figure 4.

Behaviour of the specimens

In all cases, with the increase of vertical load, the horizontal displacement at the middle of the specimen increased, thus, increasing second order bending moments in the loaded plate. In some series, the magnitude of the displacement is strongly related to the initial imperfections given in Table 4. In some cases, the initial displacement developed in one direction; however, at a certain load level it started to deform in the opposite direction. This might be explained by the form of the initial imperfections. For some specimens, a twisted shape of the plate was observed.

Figure 3

Test setup: a) schematic representation of sample test setup b) specimen of series 30_18 in the test rig (1 – steel plate, 2 – plywood layer, 3 – M4 threaded rod connector, 4 – double acting roller support, 5 – displacement transducer, 6 – roller support)

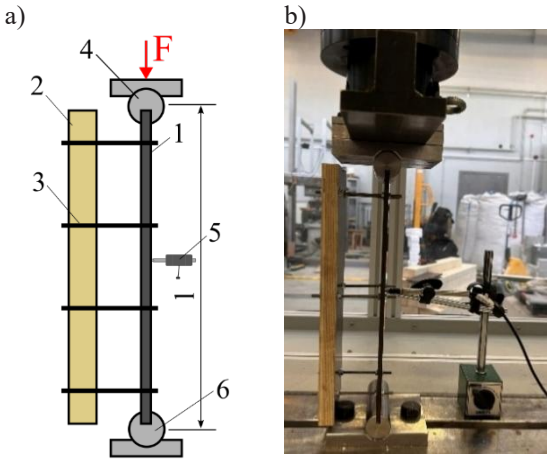


Table 4

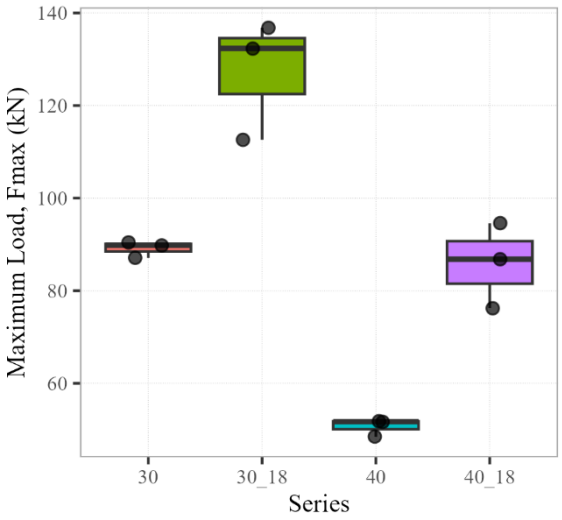
Steel plate initial imperfections

Series	Imperfections, mm		
	Specimen		
	1	2	3
30	0.25	0.1	0.15
30_18	0.2	0.09	0.15
40	0.25	0.2	0.25
40_18	0.1	0.4	0.5



All of the specimens failed by reaching the yield strength of the steel, except for series 40, where elastic buckling was observed. The specimens of the series 30 failed at the middle of the height, resulting in plastic deformations as it is seen in Figure 7, which corresponds to the section of maximum second order moment. The strengthened specimens of series 30_18 and 40_18 show higher load bearing capacity if compared to the corresponding plain plates without any strengthening. The specimens failed at a section between the horizontal connectors, not in the middle of the height of the specimen. That shows that the adjacent plywood slab and the horizontal connectors provided horizontal supports stiff enough to prevent the slender steel plate from buckling.

Maximum load

The plain plate series 30 achieved a mean maximum load of 89.1 kN with a standard deviation of 1.75 kN,

indicating highly consistent behaviour among the three specimens. Similarly, the plain plate series 40 showed a mean maximum load of 50.7 kN with a standard deviation of 1.94 kN, confirming good repeatability.
The strengthened plate series 30_18 achieved a mean maximum load of 127.2 kN, an increase of approximately 43% over the plain plate series 30. However, the standard deviation of 12,87 kN was notably higher, reflecting greater variability among the specimens. The strengthened plate series 40_18 achieved a mean maximum load of 85.9 kN, corresponding to an increase of approximately 69% relative to the plain plate series 40, with a standard deviation of 9.21 kN.
The coefficient of variation (CV) is used to measure the consistency of results within each series. The plain plate series showed low variability, with CV values of 2.0% for series 30 and 3.8% for series 40, resulting in an average CV of 2.9% for the plain plate series. In contrast, the strengthened plate series exhibited considerably higher variability, with CV values of 10.1% for series 30_18 and 10.7% for series 40_18, giving a mean CV of 10.4%. This difference in variability between plain and strengthened plates can be attributed to uncertainties in the strengthening system - specifically, the inherent material variability of birch plywood and the precision of the mechanical fasteners.

Figure 4
Maximum load by specimen series

The load–horizontal deflection curves for all series are shown in Figures 7 and 8. For the plain series 30, all three specimens displayed similar behaviour: horizontal deflections increased gradually with load, reaching a maximum of approximately 2 mm at peak load, followed by a gradual post-peak decline characteristic of elastic-plastic buckling. The strengthened plate series 30_18 achieved notably higher peak loads while maintaining similar horizontal deflections at failure – about 2 mm, indicating that the plywood layer effectively restrained lateral displacement and delayed the onset of buckling. For the plain plate series 40, the specimens developed larger horizontal deflections of up to 6 mm before failure, with no signs of material yielding, which is characteristic of elastic buckling. The strengthened series 40_18 also showed higher peak loads, but with a different lateral deflection response of approximately 4–5 mm. The samples of observed failure modes are illustrated in Figures 5 and 6.

Sandwich walls

The results of this study demonstrate that the load-bearing capacity of slender steel plates under axial compression can be improved by attaching an adjacent unloaded plywood layer. The bending stiffness of the steel plate is $E_s I_{s,z} = 21875\ kNmm^2$, while the bending stiffness of the 18 mm birch plywood layer is $E_{pl} I_{pl,z} = 486000\ kNmm^2$, which is 2.2 times stiffer than the steel plate.

This suggests that non-composite connections between the loaded and its adjacent unloaded layers can be used to design SW with more economic cross-sections. As a result, SW structures with increased load bearing capacity and the advantages of non-composite cross-section (no bowing effect, more simple connections) can be obtained. These experimental findings align with the numerical results reported by Skadins et al. (2023), where the results of numerical analysis showed that SW with non-composite connections between the loaded and adjacent layers can increase the load-bearing capacity of SW panels by delaying the onset of buckling.

To apply the findings to real SW, a further research is needed. There are several parameters that could influence the load bearing capacity. Some of them are: 1) stiffness of the adjacent layer compared to the loaded one; 2) axial stiffness and spacing of the connectors; 3) presence of the insulation layer and its mechanical properties. The root cause of these uncertainties must be clearly understood.

Conclusions

1. The proposed hypothesis is confirmed: small-scale experimental testing confirmed that adding an

unloaded plywood layer connected to the loaded steel plate with non-composite mechanical fasteners enhances the load-bearing capacity of the slender steel plate under axial compression – by 43 % for 300 mm specimens and 69 % for 400 mm specimens.

2. Pure elastic buckling failure was observed only in the plain plate series with a height of 400 mm. In all other series, the failure was governed by the second-order moments, resulting in plastic deformations at a critical section.

3. A clear correlation was observed between the size of initial geometric imperfections and the lateral deformation response during loading. In several specimen series, larger initial imperfections led to increased horizontal displacements at similar load levels, affecting the development of second-order bending moments and the ultimate failure load. However, this trend was not consistent across all series, indicating that other factors like connector accuracy and plywood variability also played a role in the observed behaviour.

4. The results confirm that even non-composite connections between the loaded and adjacent unloaded layers can substantially enhance buckling stability. This has practical implications for the design of thin-layer sandwich wall panels, where mechanical fastening creates a similar non-composite interaction between structural and non-structural layers.

5. Further research is necessary to evaluate how key parameters affect the load-bearing capacity of sandwich wall panels with non-composite connection, including (1) the relative bending stiffness of the adjacent layer relative to the loaded layer, (2) connector axial stiffness and spacing, and (3) the presence and mechanical properties of the insulation layer.

IMPACT OF UNIFORMLY DISTRIBUTED LOAD TYPES ON DEFLECTION OF SFRC FLAT SLABS

***Solvita Šņore, Ulvis Skadiņš**
Latvia University of Life Sciences and Technologies, Latvia

Abstract
In full-scale tests conducted in 2023 on two steel fibre-reinforced concrete (SFRC) and steel fibre-reinforced self-stressing concrete (SFRSSC) flat slabs, a cumulative increase in deformation and cracking was observed due to daily temperature variations. Slabs measuring 15 × 16 m and 150 mm thick were loaded with a uniformly distributed load (UDL) of 26 kN/m^2 using sandbags as the loading unit. Deformations due to daily temperature variations increased stepwise, and after 7 days of sustained loading, deflections increased by 2.5 times for the SFRC slab and 2 times for the SFRSSC slab, rising from 3.6 to 9 mm and from 3.1 to 6.5 mm, respectively. In 2024, similar tests were conducted on identical slabs to those in 2023. Two slabs were loaded with a uniformly distributed load of 30 kN/m^2 using concrete blocks arranged with a gap between them to prevent arching. Deflections were monitored along with the temperature variations over time. After the load was applied, the instantaneous deflections of both slabs were about 1.0 mm. Over the next five months, deformations increased by only 0.4 mm. Instead of the stepwise increase seen in the previous test, a cyclic daily fluctuation in deformations was observed due to temperature variations. After cracking, deflections increased over five months for about 2.6 mm (0.13 mm per week) for SFRC and 1.6 mm (0.08 mm per week) for SFRSSC slabs, respectively. Those findings indicate that the type of loading may influence long- term deflection and cracking of slabs.
Keywords: full-scale test, long-term load, steel fibre reinforced concrete (SFRC), temperature load, creep.

Introduction

Experimental tests on full-scale elevated steel fibre reinforced concrete (SFRC) slabs are reported in several scientific papers (Destrée et al., 2019) and reports (ACI Committee 544, 2015). Most of these tests focus on the instantaneous behaviour of the slabs under a point load (Aidarov et al., 2021; Parmentier et al., 2016). Several tests have been performed using uniformly distributed loads (UDL) (Popescu & Täljsten, 2023; Suta et al., 2024). However, few experimental studies have reported analyses of the long-term behaviour of SFRC slabs subjected to UDL (Aidarov et al., 2021; Salehian & Barros, 2015). While some tests show stable deflections (Aidarov et al., 2021; Salehian & Barros, 2015), others report significant increases in deflections over time (Popescu & Täljsten, 2023; Skadiņš et al., 2024).

Several processes or conditions cause time-dependent effects in SFRC slabs: 1) creep of concrete subjected to compression results in an increase in deflections over time; 2) creep of a cracked section of SFRC causes further widening of cracks (Abrishambaf et al., 2015; Casucci et al., 2019); 3) cyclic loading can increase crack width over time due to the irreversible part of the crack opening and closing process (Boulekbache et al., 2016; Menna et al., 2023; Sherif et al., 2018); 4) combination of the above-mentioned processes, e.g., combined action of cyclic loading and creep (Kern et al., 2021, 2024; Koh et al., 1997).

Cyclic loading is induced by temperature and solar radiation, causing differences in elongation between the top and bottom surfaces (Zhang et al., 2025). These differences result in bending moments and deflections of the slab. Both solar radiation intensity and temperature fluctuation throughout the day, driving daily temperature load cycles. Due to these daily cycles, a stepwise increase in deflections and crack widths was observed in two elevated SFRC/SFRSSC test slabs in Jelgava, Latvia, in 2023 (Skadiņš et al., 2024, 2026), with deflections increasing from 3 mm to 9 mm over a single week. The authors of the study suggest that this may be due to the arrangement of the UDL, achieved with tightly packed sandbags that can prevent slabs from returning to their original shape once the imposed temperature load is removed, resulting in an arching effect.

To confirm the hypothesis that the observed increase in deflections was mainly due to the way the load was applied, another pair of SFRC/SFRSSC slabs was tested a year later under a UDL using concrete blocks with gaps between them to prevent the arcing effect. The load was sustained for more than a year, and data on deflections and daily temperature variations were recorded and compared to the previous tests.

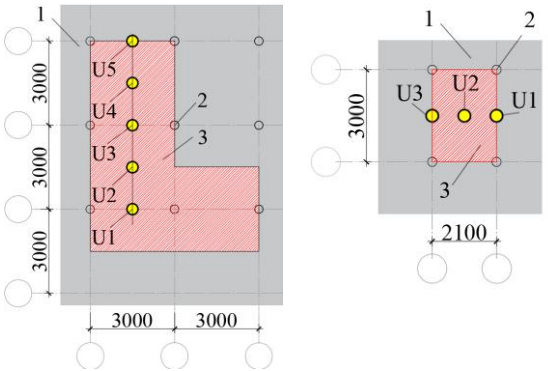
The aim of this study is to evaluate the effect of load arrangement on the behaviour of flat slabs subjected to cyclic loading, based on the results from the two pairs of full-scale experimental tests mentioned above, comparing the relationship between deflection behaviour and temperature variations.

Materials and Methods

In 2023, two full-scale slabs (later referred to as SFRC-1 and SFRSSC-1) were produced and tested in Jelgava, Latvia. Dimensions of the slabs were 15 × 16 m in the plane and 150 mm in thickness. The slabs were supported by round reinforced-concrete columns 300 mm in diameter, with spans up to 3 m. More detailed descriptions of the slabs are published by Suta et al. (2024). The concrete design for both slabs was identical, except for a chemical component that introduced the prestressing effect. One cubic meter of concrete mix contains 360 kg of CEM II/A-LL 52,5, 162 kg of water (w/c ratio 0.45), 952 kg of sand, 914 kg of dolomite gravel (5 – 16 mm), 3.6 kg of admixture PrīmX Flow HRWRA, 50 kg of 60 mm long 0.9 mm in diameter hooked-end steel fibres as an only reinforcement of the slab, and 40 kg PrīmX DC (only

for SFRSSC-1).

A load level of 26 kN/m² was achieved using sandbags as the loading units (Figure 2a). Each bag weighed 10 kN, and they were arranged in three layers. Deflections of the slab were measured using linear displacement transducers with a measuring range of 75 mm. There were five sensors that took measurements at different locations on the bottom surface of the slab (Figure 1a). A pair of Rissfox Mini data loggers with Rissfox Multisensor expansion modules was used to collect the data. Along with the slab deflection, the temperature near the bottom layer of the slab was also recorded.



The following year, similar tests were conducted on two slabs that were geometrically identical to those in 2023 (later referred to as SFRC-2 and SFRSSC-2). The design of both slabs was the same, except for a chemical component that provided the prestressing effect. One cubic meter of concrete mix contains 360 kg of CEM II/A-LL 52,5, 165 kg of water (w/c ratio 0.467), 783 kg of sand, 1091 kg of dolomite gravel, 3.24 kg of admixture PrīmX Flow HRWRA, 50 kg of 60 mm long 0.9 mm in diameter hooked- end steel fibres, and 40 kg of PrīmX DC (only for SFRSSC-2). No complementary reinforcement was added.

Slabs were loaded with concrete blocks (Figure 2b) measuring 600×600×600 mm. Each block weighed 5.20 kN, and they were arranged in three layers, creating a uniformly distributed load of 30 kN/m^2. Blocks were placed with a gap between them to prevent arching effects.

Deflections of the slabs were measured at three points at the bottom surface of the slabs using the same linear displacement transducers as in the 2023 tests. The loading area and sensor arrangement are shown in Figure 1b.

Figure 1

Arrangement of deflection sensors U1...U5 on slabs: a) SFRC-1 and SFRSSC-1 and b) SFRC-2 and SFRSSC-2 (1 – slab; 2 – column; 3 – loaded area)

a) b)

Concrete material properties, such as compressive and post-cracking flexural strength, were obtained from specimens produced alongside the full-scale slabs. The obtained material properties are shown in Table 1.

Compressive strength was determined in accordance with EN 12390-7 using 300 mm high concrete cylinders with a diameter of 150 mm.

Table 1

Material properties

Property	SFRC-1		SFRC-2		SFRSSC-1		SFRSSC-2	
	Value	CoV, %	Value	CoV, %	Value	CoV, %	Value	CoV, %
Compressive strength, MPa	41.03	4.3	50.90	2.9	49.29	1.6	52.80	5.1
Post-cracking flexural strength, MPa								
$f_{R,L}$	4.93	8.1	5.43	6.0	6.63	4.3	6.03	7.0
$f_{R,1}$	5.13	18.2	5.32	32.0	7.83	15.4	6.27	21.0
$f_{R,2}$	6.18	14.1	6.35	36.0	9.38	10.3	7.00	20.0
$f_{R,3}$	6.13	9.7	6.18	34.0	8.66	9.4	6.95	18.0
$f_{R,4}$	6.10	10.1	5.85	32.0	8.05	15.2	6.57	22.0

Figure 2

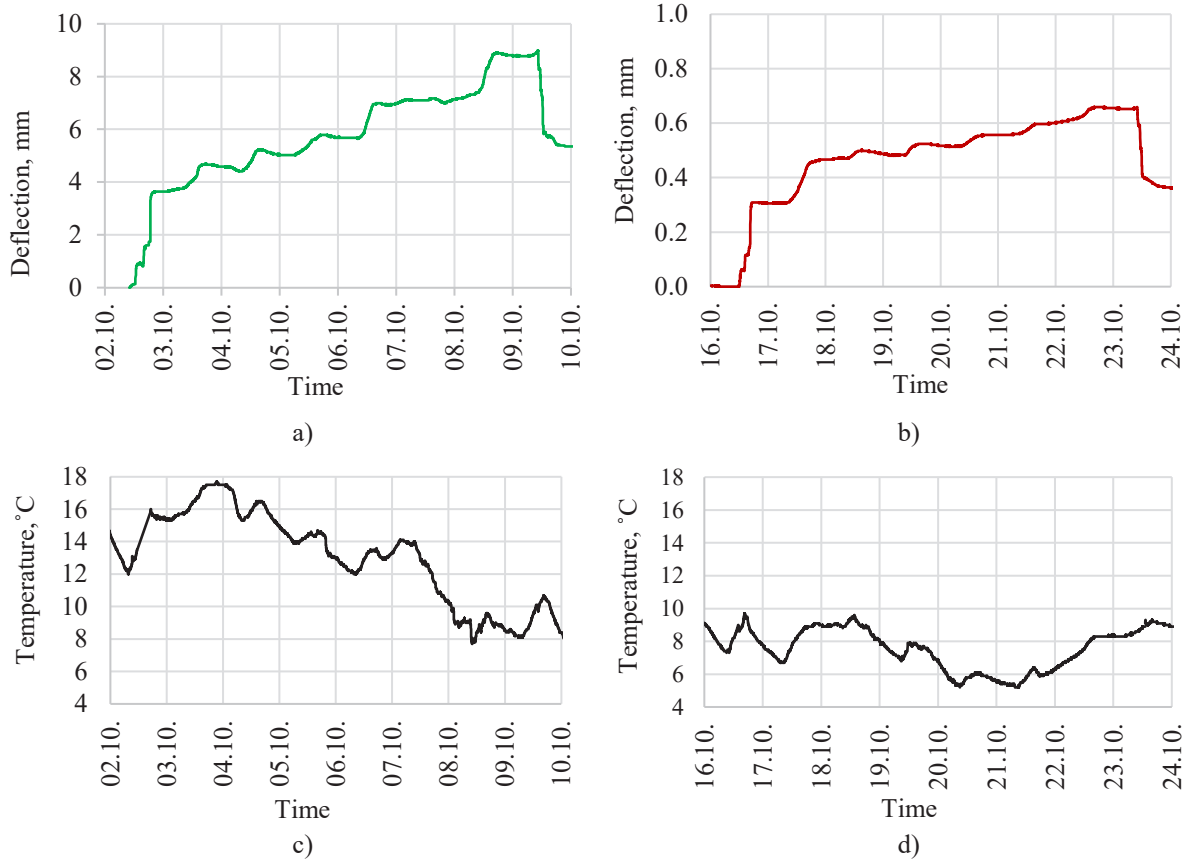
a) b)

For loading, a Matest hydraulic press (2000 kN, Class 1) was used. The post-cracking flexural strength was determined in accordance with EN 14651 using concrete prism specimens subjected to three–point bending tests. The specimens were tested in the Matest Hydraulic press (Form + Test Delta 5-300, Class 1). The tests were controlled by crack mouth opening displacement (CMOD) using a Pi- shape displacement transducer, PI-5-50 (Tokyo Measuring Instrument Lab), with a gauge length of 50 mm.

Results and Discussion

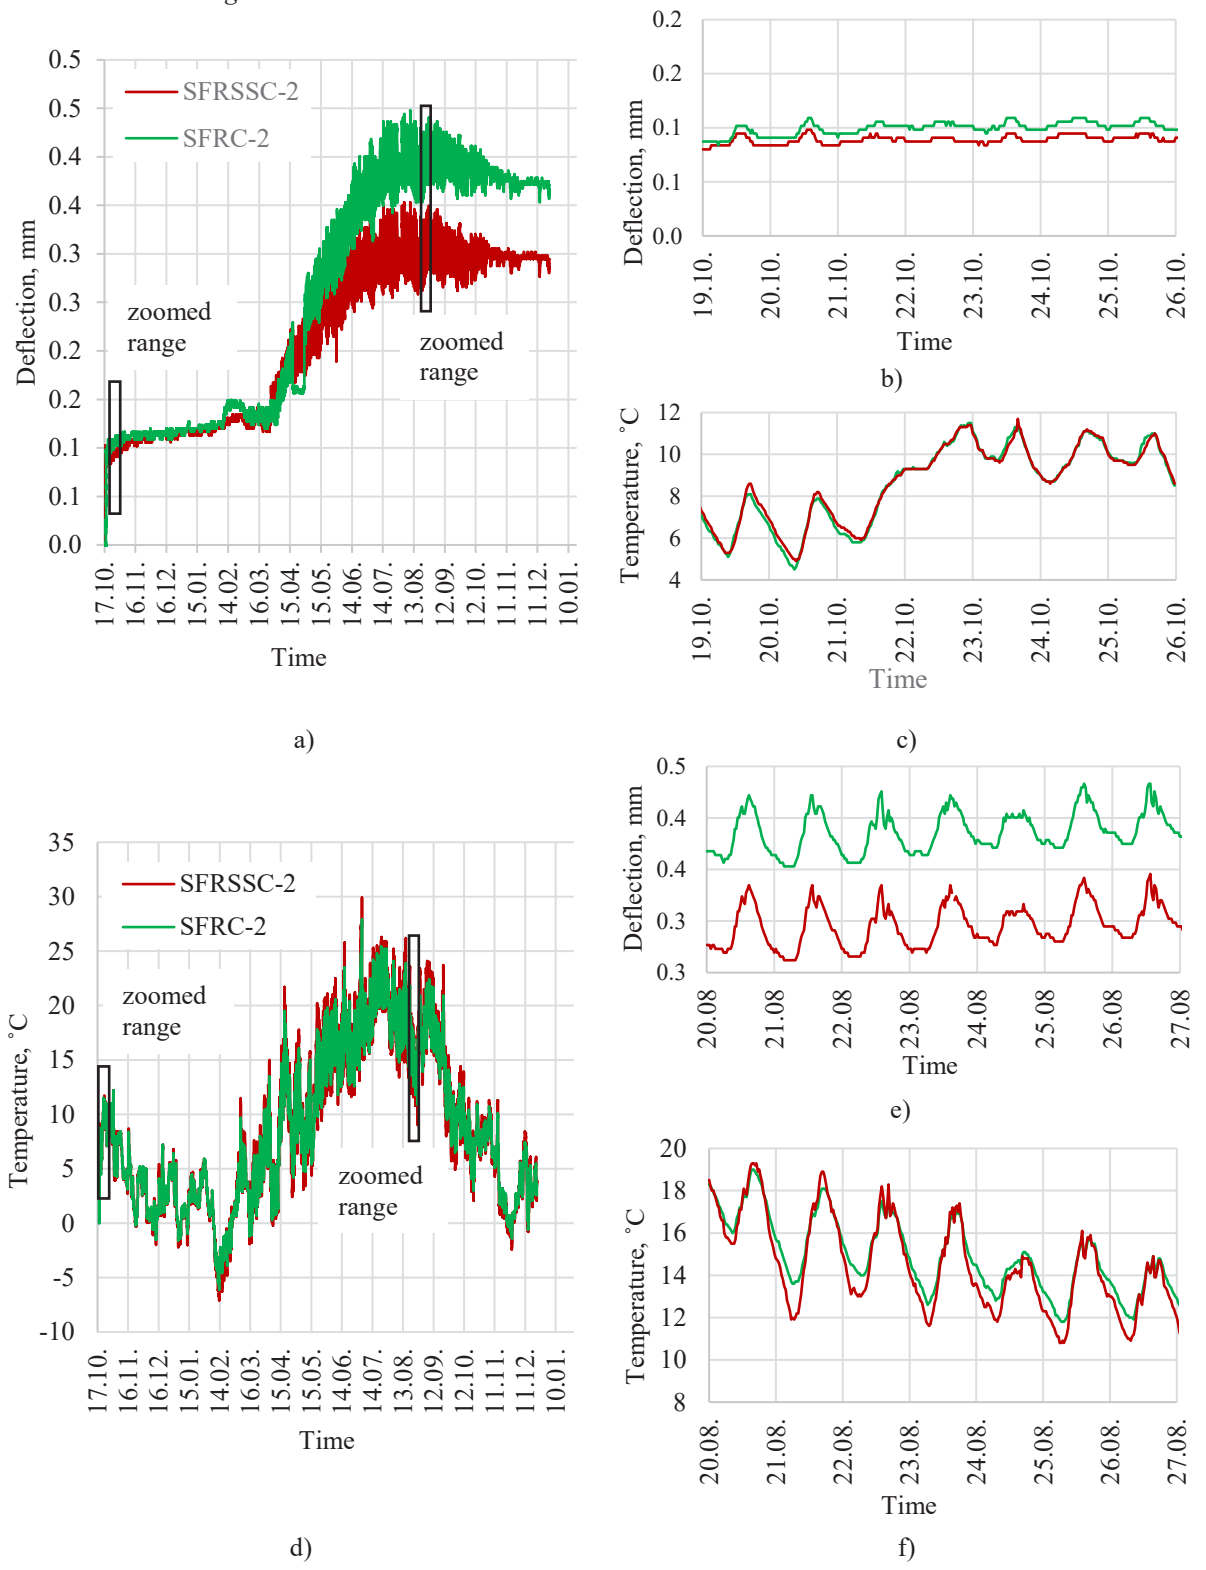


The deflection comparison is analysed at position U2 (Figure 1), which is in the middle of the spans, where the largest deformations were observed.

In 2023, deformations gradually increased due to daily temperature fluctuations. After 7 days of sustained loading, deflections increased stepwise by 2.5 times for the SFRC-1 slab and by 2 times for the SFRSSC-1 slab, rising from 3.6 to 9 mm and from 3.1 to 6.5 mm, respectively (Figure 3). The temperature variations during the week were 10 °C for the SFRC-1 slab and 5 °C for the SFRSSC-1 slab, with a decreasing trend. The daily variations in surface temperature during that period ranged from 2.0 to 2.5 °C. During the daytime, when the temperature increases by 1 °C, deformations grow by 1 mm for the SFRC-1 slab and by 0.3 to 0.5 mm for the SFRSSC-1 slab. During the night, when the temperature dropped by about 2.5 °C, deformations decreased by only 0.1 – 0.15 mm. After the load was removed, irreversible deformations measured 5.1 mm for the SFRC-1 slab and 3.6 mm for the SFRSSC-1 slab.

In the 2024 test, after the load was applied, the instantaneous deflections of both slabs were approximately 1.0 mm (Figure 4a), and no cracks were observed. After one week of sustained loading, deformations fluctuated during the daily temperature variations, but showed no increase in general. The temperature variations during the first week of the test were 7.5 °C. The daily fluctuations in surface temperature during that period ranged from 3 to 4 °C (Figure 4c). During the daytime, when the temperature increased by 4 °C, deformations increased by 0.2 to 0.3 mm and decreased by the same amount at night (Figure 4b). Instead of the stepwise increase seen in the previous test, a cyclic daily fluctuation in deformations was observed. Over the next five months, deformations increased by only 0.4 mm. After cracking, deflections increased over five months for about 2.6 mm (0.13 mm per week) for SFRC-2 and 1.6 mm (0.08 mm per week) for SFRSSC-2 slabs.

Figure 3



Recorded variations of: a) deflections at the midspan (U2) of SFRC-1, b) deflections at the midspan (U2) of SFRSSC-1 and c), d) temperature

In the cracked stage, the slabs' deformations due to the daily temperature fluctuations showed the same cyclic pattern as in the uncracked stage, instead of the stepwise pattern observed in the test in 2023 (Figures 4e and 4f). The temperature variations during the week of long-term loading were 7–8 °C. The daily fluctuations in surface temperature during that period ranged from 4 to 7 °C During the daytime, when the temperature increases by 7 °C, deformations grow by 0.7 to 0.8 mm.

Figure 4

Recorded variations of: a) deflections at the midspan (U2), d) temperature and b), c), e), f) corresponding zoomed one-week range

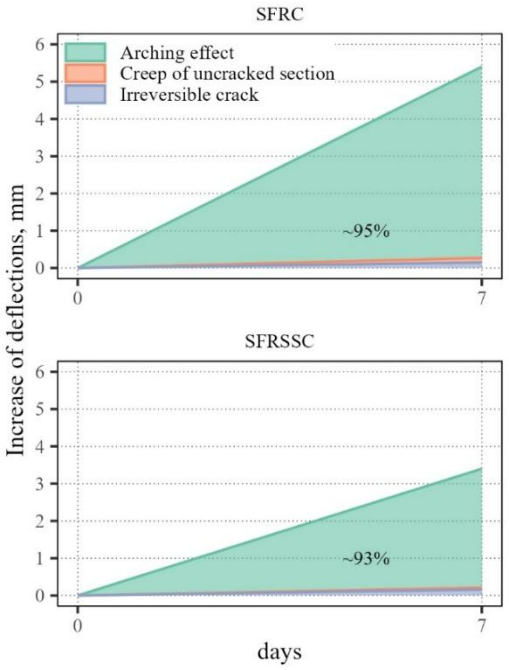
To compare the results and evaluate the influence of creep (Equation (1), irreversible cracking (Equation (2), and loading type (Equation (3)) in 2023 tests, the week deformations from the 2024 tests for cracked and uncracked concrete are compared with the total deformations over a week period in the 2023 tests.

$$u_{creep} = \frac{\Delta_{u,week,creep,2024}}{\Delta_{u,week,total,2023}} \cdot 100\% \quad (1)$$

$$u_{irr} = \frac{\Delta_{u,week,irr,2024}}{\Delta_{u,week,total,2023}} \cdot 100\% \quad (2)$$

$$u_{LT} = 100\% - (u_{creep} - u_{irr}) \quad (3)$$

where u_{creep} – deformations caused by creep; u_{irr} – deformations caused by irreversible cracking, u_{LT} – deformations caused by loading type (tightly packed sandbags), $\Delta_{u,week,total,2023}$ – total deformations over a week period in 2023, $\Delta_{u,week,creep,2024}$ – deformations in 2024 tests over a week period caused by creep (uncracked concrete), $\Delta_{u,week,irr,2024}$ – deformations in 2024 tests over a week period caused by irreversible cracking (cracked concrete).



A creep effect on the deflections of the slabs tested in 2024 can be observed. In the uncracked stage, the deflections increased by about 40% (from 1.0 mm to 1.4 mm) over five months. This could be caused by creep deformations in the compression zone, resulting in an increase in the curvature. Although the observed increase developed faster in the first month, it is rather small, with a 0.05–0.12 mm increase in the first week of loading, which is 2% of the increase observed in the 2023 test.

In the cracked stage of the 2024 test, an increase in deflections is observed as well. This could be attributed to either creep of the cracked SFRC section (Abrishambaf et al., 2015; Casucci et al., 2019) and/or the partly irreversible nature of SFRC at cracks subjected to cyclic loading (Boulekbache et al., 2016; Menna et al., 2023; Sherif et al., 2018). However, the magnitude of the increase in deflections over a single week is just about 0.15 mm (Figure 4e), which is 3–5% of the increase observed in the 2023 test.

Based on the data obtained from the 2024 test, the total contribution of creep and the irreversible nature of the cracked section to the increase in deflections in the 2023 test could be about 5 –7 %. The value should be adjusted considering the differences in material properties and the level of normal stresses developed in both tests. However, these effects represent only a small fraction of the observed increase (Figure 5). The comparison of results from both tests shows that the UDL arrangement has a significant influence on the time-dependent load–deflection behaviour of flat slabs. Given that similar load levels were applied and concrete with similar compressive strength was used in both tests, the interaction effect between the deformed slab and the tightly packed sandbags, as suggested by Skadiņš et al. (2024), is the most plausible explanation of the extremely large increase in deflection over a single week.

These findings are important not only for the design of full-scale tests, but also for structures loaded with sand-like materials and subjected to daily temperature variations. Such structures might include retaining walls, outdoor material storage facilities, raft foundations for car parks, and others. To better explain the observed increase in deflections of cracked slabs in the 2024 test, further long-term tests are needed, where the effect of cyclic loading on the creep of cracked SFRC sections is evaluated.

Figure 5
Possible causes of increased deformation in slabs

Conclusions

In this study, the effect of load arrangement on the behaviour of flat slabs subjected to cyclic loading, based on the results from the two pairs of full-scale experimental tests, was evaluated, and the relationship between deflection behaviour and temperature variations was compared. The following conclusions can be made:

1. Deflections of the slabs loaded with tightly packed sandbags increased with the increase of daily temperature, showing no recuperation of the deflection after the drop in temperature.
2. Deflections of the slabs loaded with concrete blocks with gaps between them increased and decreased following the pattern of the temperature variations – no significant accumulation of deflections over a period of a week was observed.
3. Those findings indicate that the type of loading influences long-term deflection and cracking of slabs.
4. Further investigation should be conducted to observe the possible creep effects, excluding the daily temperature fluctuations.

LONG-TERM CHANGES IN ARABLE LAND, MEADOWS AND NATURAL PASTURES, ORCHARDS IN LITHUANIA

Abstract
The analysis is based on official statistical data covering the period 2005–2025 and includes Lithuania and its ten counties. Using statistical analysis and grouping methods, the structure of land use and its temporal changes were assessed, with particular attention to arable land, meadows and natural pastures, and orchards. The results reveal a clear transformation of Lithuania's agricultural land-use structure. Arable land remains the dominant form of land use and its share and importance have increased over time, confirming a long-term trend of agricultural intensification of land-use systems. In contrast, the areas of meadows and natural pastures, as well as orchards, have significantly declined, indicating a gradual weakening of extensive land-use forms and a reduction in land resources important for livestock farming and traditional rural landscapes. Territorial differences among counties persist and highlight a pronounced regional differentiation of land-use structures. Arable land is more dominant in regions characterized by intensive agricultural activity, whereas the relative proportion of meadows, natural pastures, and orchards remains higher in less intensively used areas. These spatial patterns indicate ongoing landscape homogenization alongside continued restructuring of rural land-use systems. The study demonstrates a consistent shift towards a land-use structure increasingly dominated by arable land in Lithuania, accompanied by the decline of meadows, natural pastures, and orchards, as well as the strengthening of regional land-use differentiation.
Keywords: land-use change, structure of agricultural land, change in agricultural land areas.

Introduction

Changes in the structure of agricultural land constitute one of the key indicators of territorial development, landscape transformation, and sustainability. Scientific literature emphasizes that land-use change reflects not only economic processes but also political decisions, technological progress, demographic trends, and societal attitudes toward environmental protection (Turner et al., 2007; Lambin & Meyfroidt, 2011). It is therefore particularly important to analyze the dynamics of individual agricultural land categories—arable land, meadows and natural pastures, and orchards—because changes in each category have distinct effects on ecosystem functions, biodiversity, and landscape structure.

At the European scale, changes in agricultural land use, particularly shifts in arable land, meadows and natural pastures, and perennial land uses such as orchards, are associated with ongoing landscape transformation processes that may contribute to the reduction of semi-natural habitats and changes in the structural diversity of agricultural landscapes (Plieninger et al., 2016; European..., 2017).

In the scientific literature, changes in arable land—often linked to agricultural intensification driven by economic pressures, technological development, and market forces—are closely associated with the restructuring of agricultural land-use systems. Within this process, intensified production practices, particularly in arable farming, are commonly characterized by increased use of agrochemicals and mechanization, which can contribute to changes in soil properties and affect the ecological stability of agricultural landscapes, including adjacent semi-natural land-use types such as meadows, natural pastures, and orchards (Foley et al., 2011; Tilman et al., 2011).

Studies at the European Union level show that arable land areas increase or remain stable in the most productive regions, whereas in areas less favorable for agriculture they decline due to land abandonment or natural succession processes (Eurostat, 2023).

The Common Agricultural Policy (CAP) is considered one of the most influential factors shaping arable land dynamics in Europe. Direct payments and investment support have promoted the expansion of crop production and farm specialization, particularly in Central and Eastern European countries (Pe'er et al., 2019). Research indicates that the CAP has also indirectly contributed to the ploughing of grasslands and the simplification of landscape structure (Stoate et al., 2009).

Lithuanian scientific studies indicate that after 2004, the expansion of arable land became the most economically attractive form of land use, especially in fertile regions (Stravinskienė et al., 2015; Vitunskienė, 2018).

Meadows and natural pastures represent important components of agricultural land-use systems alongside arable land and orchards, forming semi-natural land-use types that contribute to landscape diversity. These land categories are typically maintained through extensive agricultural practices, particularly livestock grazing and low-intensity management, and their persistence is closely linked to changes in agricultural land-use structure and farm specialization processes (Habel et al., 2013; Eurostat, 2025).

Europe has diverse natural and semi-natural grasslands shaped by long-term human–nature interactions, serving as biodiversity hotspots and cultural heritage. Despite their large extent, only about half are of high

nature value, and ongoing decline and fragmentation are driven by agricultural intensification, abandonment of traditional farming, and urbanization. Under Anthropocene conditions, these ecosystems are experiencing increasing pressure, highlighting the need to reassess conservation and restoration strategies (Mahy et al., 2024).

The literature identifies two main pathways of grassland decline: intensification and abandonment. Intensification manifests through the conversion of grasslands into arable land, while abandonment leads to natural succession in areas less suitable for agricultural production (Plieninger et al., 2016).

Stoate et al. (2009) emphasize that the decline of livestock farming is one of the most important factors contributing to the loss of meadows and pastures. Lithuanian studies further show that these processes are particularly pronounced in regions dominated by crop production specialization (Stravinskienė et al., 2015).

Orchards represent an important component of traditional agrarian landscapes, contributing to structural diversity, aesthetic values, and the preservation of cultural heritage (Plieninger & Bieling, 2012). Although orchards typically occupy a relatively small share of agricultural land, their ecological significance is disproportionately high. Orchards provide a wide range of ecosystem services, including biodiversity conservation and soil carbon sequestration (Demestihas et al., 2017). Traditional orchards are a key feature of Central European cultural landscapes with high ecological value; however, their extent is rapidly declining (Grosse-Stoltenberg et al., 2024).

Many authors agree that the long-term dominance of arable land, combined with the decline of grasslands and orchards, reduces landscape ecological resilience and increases the risk of soil degradation and biodiversity loss (Lal, 2015; Pe'er et al., 2019). Consequently, contemporary literature increasingly emphasizes the concept of multifunctional and integrated land use, which seeks to balance economic, ecological, and social objectives (Eurostat, 2025).

Agriculture represents a dominant form of land use, and its structural transformation has direct implications for the balance between arable land, meadows and natural pastures, and orchards. The shift from traditional, extensive land-use practices toward more intensive and specialized agricultural systems has contributed to changes in land-use structure, including the decline of semi-natural land-use types and the increasing dominance of arable land. These processes may increase the dependence on external inputs and reduce the resilience of agricultural landscapes at regional scale (Agnoletti & Santoro, 2022).

An extended review of the scientific literature demonstrates that changes in the areas of arable land, meadows and natural pastures, and orchards are complex processes reflecting interconnected economic, policy, and socio-demographic drivers, which jointly shape the long-term restructuring and spatial differentiation of agricultural land-use systems. Despite extensive literature on land-use change in Lithuania and Europe, existing studies predominantly focus on national-scale trends or individual land-use categories, while systematic comparative analyses at the county level remain limited. Consequently, there is insufficient understanding of spatially differentiated land-use dynamics within Lithuania, particularly regarding how arable land, meadows and natural pastures, and orchards vary across counties and contribute to regional land-use restructuring. This study addresses this gap by providing a consistent county-level assessment of land-use change over the 2005–2025 period.

The novelty of this research lies in its systematic long-term comparative analysis of land-use changes across all ten Lithuanian counties. Unlike previous studies that mainly emphasize national-scale trends or single land-use categories, this study integrates spatial differentiation and simultaneously evaluates the dynamics of arable land, meadows and natural pastures, and orchards. This approach enables a more detailed understanding of regional heterogeneity in land-use transformation and reveals spatial patterns of agricultural restructuring that are not evident in aggregated national statistics.

The object of the study is the structure and dynamics of agricultural land use in the Republic of Lithuania, including arable land, meadows, natural pastures, and orchards, over the period 2005–2025.

The aim of the study is to analyze changes in the extent and distribution of different types of agricultural land in Lithuania and its counties between 2005 and 2025, and assess the factors driving these changes.

1. To analyze the current state of arable land, meadows and natural pastures, and orchards in Lithuania and its counties.
2. To examine the changes in the areas of arable land, meadows and natural pastures, and orchards between 2005 and 2025.
3. To identify the causes of changes in the analyzed land areas.

Materials and Methods

The analysis was based on official Lithuanian national statistical data on the area and structure of agricultural land for the period 2005–2025 (ZISIS, 2005–2025). The dataset includes the total area of agricultural land (ha), as well as the areas of arable land, meadows and natural pastures, and orchards by county (ha). The data were processed at both county and national levels. The analysis covered all ten counties of Lithuania: Alytus, Kaunas, Klaipėda, Marijampolė, Panevėžys, Šiauliai, Tauragė, Telšiai, Utena, and Vilnius.

Data processing was carried out at both county and national levels. County-level values were aggregated from official statistical records, and consistency checks were performed to ensure comparability across the study period.

Descriptive statistical analysis methods were applied in the study, and a grouping method was used for the preparation of the article.

Changes in land-use area were calculated using absolute and relative indicators. Absolute change (Δha) was calculated as, Formula 1:

$$\Delta ha = A_{(2025)} - A_{(2005)} \quad (1)$$

Percentage change (%) was calculated as, Formula 2:

$$\% \text{ change} = [(A_{(2025)} - A_{(2005)}) / A_{(2005)}] \times 100 \quad (2)$$

where $A_{(2025)}$ and $A_{(2005)}$ represent land-use areas in the respective years.

Lithuanian counties were grouped according to the percentage share of arable land and meadows and natural pastures. Classification thresholds were defined based on the distribution of empirical data and in accordance with approaches used in previous Lithuanian land-use studies applying similar proportional classification methods, ensuring comparability and interpretability of regional differences.

The grouping scheme was as follows: arable land—high (>55%), medium (44–54%), low (<44%); meadows and natural pastures—high (>6%), medium (4–6%), low (<4%). Orchards were analysed using both absolute (ha) and relative (%) indicators due to their low spatial extent and high inter-regional variability.

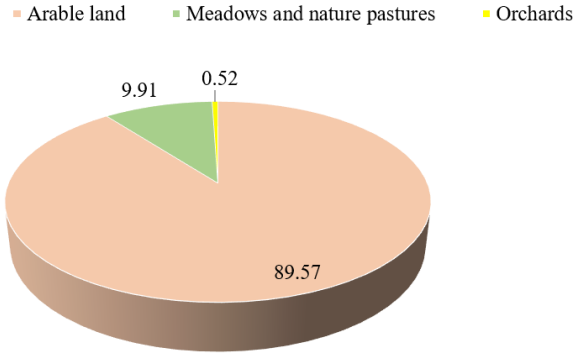
The study presents an analysis of land-use change. Changes in area (ha) and percentage change (%) were calculated. The results were visualized using bar charts and pie charts (Figures 1–7), which clearly illustrate the distribution of agricultural land, temporal changes, and the grouping of counties according to land-use intensity. The processed data are presented in tables.

Both quantitative and qualitative analyses of the drivers of land-use change were conducted, identifying the main factors behind the expansion of arable land and the decline of meadows, pastures, and orchards.

Finally, it should be noted that the study relies on secondary statistical data, which may be affected by changes in land classification methodologies over time and potential limitations in administrative data accuracy. However, the use of a harmonized national statistical database minimizes these inconsistencies and ensures overall data comparability across the study period.

Results and Discussion

Current Situation



In 2025, agricultural land in Lithuania accounted for 3,365,699.61 ha (51.55% of national territory). The structure was strongly dominated by arable land, which covered 3,014,651.09 ha (46.18% of total land area and 89.57% of agricultural land), confirming a highly crop-oriented agricultural system (Figure 1).

Semi-natural and perennial land uses remained marginal: meadows and natural pastures occupied 333,385.5 ha (5.11%), while orchards covered 17,663.02 ha (0.27%). Although limited in spatial extent, these land-use categories represent key components of ecological infrastructure, particularly in supporting habitat diversity and ecosystem functions within agricultural landscapes.

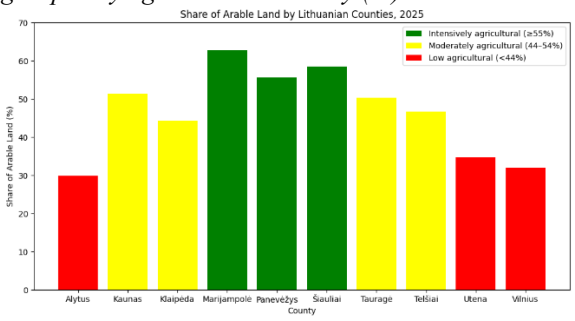
The land-use structure indicates a high degree of agricultural specialization and limited functional diversification at the national scale.

Figure 1

Distribution of agricultural land in the Republic of Lithuania in 2025 (%)

Arable land distribution in 2025 exhibited marked regional heterogeneity. High concentrations in Šiauliai, Panevėžys, and Marijampolė counties reflect favourable biophysical conditions and consolidated commercial farming systems (Table 1). Medium levels in Kaunas, Tauragė, Klaipėda, and Telšiai indicate mixed agricultural regimes, where crop production coexists with more diversified land uses. Lower shares in Alytus, Vilnius, and Utena counties correspond to less favourable conditions and more fragmented land-use structures.

Table 1



Arable land area (ha and %) by county in Lithuania, 2025

County	Arable land area in 2025 (ha)	Arable land area (%)
Alytus	161,736.73	29.87
Kaunas	414,870.21	51.33
Klaipėda	233,516.59	44.27
Marijampolė	280,164.57	62.73
Panevėžys	438,681.46	55.69
Šiauliai	499,916.71	58.55
Tauragė	221,754.54	50.32
Telšiai	203,381.35	46.77
Utena	249,319.86	34.66
Vilnius	311,309.06	32.00

(ZISIS, 2005-2025).

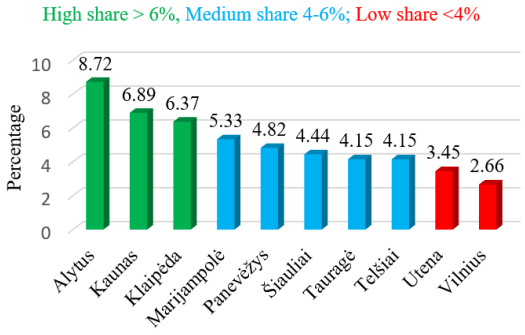
Based on these results, Lithuanian counties were classified into three groups according to the share of arable land (Figure 2): high (≥55%), medium (44–54%), and low (<44%). This classification highlights clear regional differentiation in agricultural intensity, driven by both natural conditions and land-use structure. As noted above, in 2025, *meadows and natural pastures* in Lithuania covered approximately 5.11% of the country's total area.

Figure 2
Share of arable land by Lithuanian counties in 2025, grouped by agricultural intensity (%)

Meadows and natural pastures show pronounced spatial variability across Lithuanian counties, reflecting differences in agricultural intensity and biophysical conditions (Table 2). In absolute terms, the largest areas were recorded in Utena county, while the smallest were observed in Marijampolė county (15,424.32 ha).

Figure 3 illustrates the proportion of meadows and natural pastures across Lithuanian counties in 2025. Based on their relative share, counties are classified into three groups—high, medium, and low—highlighting clear spatial differentiation in the distribution of meadow and natural pasture systems.

Table 2
Meadows and natural pastures in Lithuanian counties, 2025 (ha and % of county area)



Counties	Area of meadows and natural pastures in 2025 (ha)	Meadows and natural pastures (%)
Alytus	26,101.95	8.72
Kaunas	32,889.29	6.89
Klaipėda	36,001.98	6.37
Marijampolė	15,424.32	5.33
Panevėžys	32,729.83	4.82
Šiauliai	22,748.73	4.44
Tauragė	23,505.48	4.15
Telšiai	19,308.65	4.07
Utena	62,705.42	3.45
Vilnius	61,969.87	2.66

(ZISIS, 2005-2025).

The high-share group (Alytus, Kaunas, Klaipėda) indicates stronger persistence of extensive land-use systems. The medium-share group (4–6%) includes Marijampolė, Panevėžys, Šiauliai, Tauragė, and Telšiai counties, reflecting transitional land-use structures with a balanced mix of intensive and extensive agricultural practices. The low-share group (<4%) consists of Utena and Vilnius counties, where meadows and natural pastures are least prevalent, suggesting a higher degree of land-use intensification and reduced presence of meadows and natural pastures.

In 2025, the largest area of *orchards* was recorded in Panevėžys county (3,109.11 ha). Relatively high orchard areas were also observed in Kaunas (2,596.02 ha) and Utena (2,461.15 ha) counties, indicating localized concentrations of perennial horticultural land use. In contrast, the smallest orchard areas were found in Klaipėda (770.54 ha) and Telšiai (833.38 ha) counties, Table 3.

Figure 3
Share of meadows and natural pastures by counties in Lithuania, 2025

When expressed as a proportion of total county area, Panevėžys county again shows the highest share of orchards (0.39%), followed by Tauragė (0.35%), Utena (0.34%), and Kaunas (0.32%) counties. The lowest proportions are observed in Klaipėda county (0.15%) and in Telšiai, and Vilnius counties (0.19% each), reflecting the marginal role of orchards in the land-use structure of these areas.

Table 3
Orchard area (ha and %) by county in Lithuania, 2025

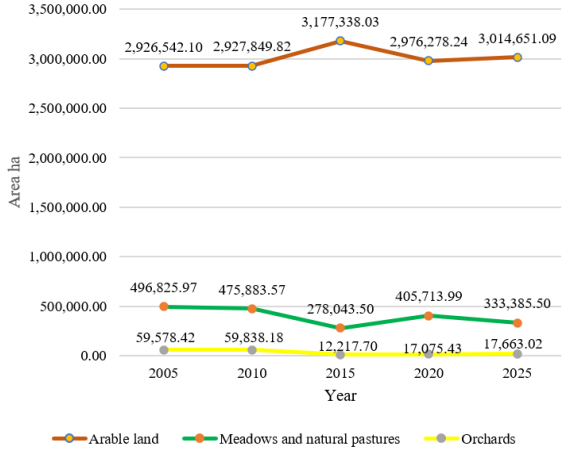
Counties	Orchard area in 2025 (ha)	Orchard area (%)
Alytus	1,183.74	0.22
Kaunas	2,596.02	0.32
Klaipėda	770.54	0.15
Marijampolė	1,313.12	0.29
Panevėžys	3,109.11	0.39
Šiauliai	2,065.86	0.24
Tauragė	1,521.2	0.35
Telšiai	833.38	0.19
Utena	2,461.15	0.34
Vilnius	1,808.92	0.19

(ZISIS, 2005-2025).

Overall, the analysis of the current land-use situation shows substantial regional variation in the share of arable land across Lithuanian counties, ranging from

29.87% in Alytus county to 62.73% in Marijampolė county. This wide range indicates that agricultural activity in Lithuania is predominantly oriented towards intensive crop production, particularly in the most productive regions.

Meadows and natural pastures account for between 2.66% in Vilnius county and 8.72% in Alytus county, reflecting generally limited allocation of land to livestock-oriented and extensive farming systems. Despite their relatively small spatial extent, these land-use types remain important for maintaining ecological stability and landscape heterogeneity.



Orchard areas vary from 0.15% in Klaipėda county to 0.39% in Panevėžys county, indicating that horticultural land use plays a minor role in the overall agricultural structure. Nevertheless, its spatial distribution suggests a supplementary but regionally differentiated contribution to agricultural diversification and rural landscape complexity.

Analysis of Land-Use Changes in Lithuania, 2005–2025

Figure 4 shows that between 2005 and 2025, the structure of agricultural land in Lithuania underwent substantial changes, characterized by a shift toward intensive farming, with increasing arable land and declining meadows, natural pastures, and orchards.

Figure 4

Changes in the area of arable land, meadows and natural pastures, and orchards in Lithuania, 2005–2025 (ha)

Source: (ZISIS, 2005-2025).

Nationally, *arable land* increased by 88,108.99 ha (+3.01%) over the study period, indicating a modest but persistent intensification trend (Table 4).

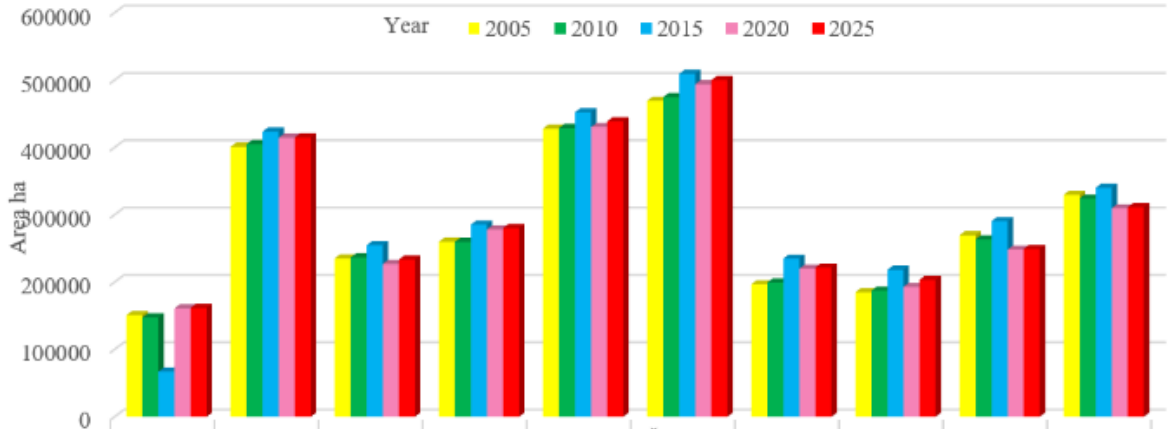
Between 2005 and 2025, the area of *meadows and natural pastures* in Lithuania declined by 163,440.47 ha (32.89%), indicating a considerable contraction of extensive land-use systems. These processes are most evident in regions with intensive agriculture, where the loss of semi-natural land covers has been greatest.

During the same period, *orchard areas* in Lithuania declined by 41,915.40 ha (70.34%). The observed decline in orchard areas reflects a broader restructuring of agricultural land use, characterized by a decreasing role of traditional perennial systems. As a result, orchard landscapes are becoming increasingly fragmented and spatially limited, with a growing tendency toward their integration into other dominant land-use types. This trend indicates a gradual shift in the functional role of orchards within the overall agricultural structure.

Table 4

Changes in arable land, meadows and natural pastures, and orchards in Lithuania, 2005–2025 (ha and %)

Land-Use Type	Change (ha)	Change (%)
Arable land	+88,108.99	+3.01
Meadows and natural pastures	-163,440.47	-32.89
Orchards	-41,915.40	-70.34



The results demonstrate a consistent long-term transformation of agricultural land structure in Lithuania, characterized by the expansion of intensively used arable land and the substantial contraction of meadows, natural pastures, and orchards. This continued transition toward increasingly specialized, production-focused land management is reshaping the structure of rural landscapes and affecting their ecological balance. It leads to a simplification of spatial patterns and a reduction in the variety of natural and semi-natural habitats. These changes may weaken ecological networks and reduce the resilience of ecosystems, while also influencing rural development pathways and limiting the multifunctional roles traditionally provided by agricultural land.

The analysis of changes in *arable land* between 2005 and 2025 at the county level indicates that arable land expanded in seven out of ten Lithuanian counties, while a decline was observed in Vilnius, Utena, and Klaipėda counties (Figure 5).

Over the 20-year period, the most pronounced relative increases in arable land were recorded in Tauragė, Telšiai, and Marijampolė counties, suggesting a strong intensification of agricultural land use in these regions. In absolute terms, the greatest expansion of arable land occurred in Šiauliai and Tauragė counties, reflecting their role as key areas of agricultural production and land-use restructuring (Table 5).

Conversely, declines in Vilnius and Utena (-5.60% and −7.55%) reflect urban pressure, land-use diversification, and partial withdrawal from intensive agriculture (Table 5). These contrasting trajectories highlight increasing spatial polarization between core agricultural regions and peri-urban or less productive territories.

Figure 5

Source: (ZISIS, 2005-2025).

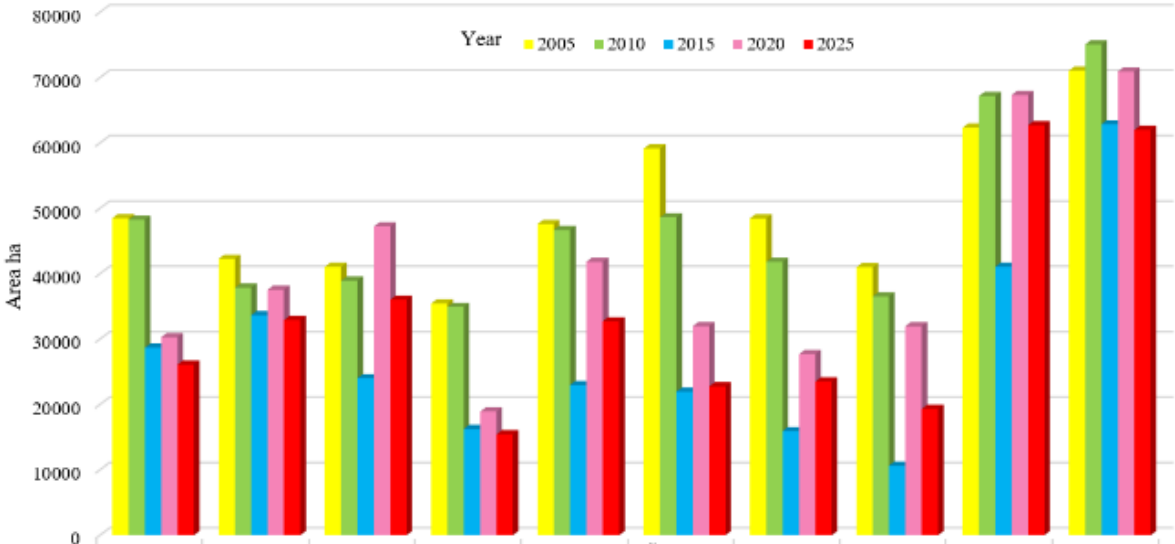
The analysis of changes in *meadows and natural pastures* across Lithuanian counties between 2005 and 2025 reveals pronounced long-term dynamics characterized by an overall declining trend interrupted by short-term fluctuations (Figure 6).

Table 5
Changes in arable land area in Lithuanian counties, 2005–2025 (ha and %)

Counties	Change (ha)	Change (%)
Alytus	+10,551.39	+6.98
Kaunas	+13,716.30	+3.42
Klaipėda	–1,865.34	-0.79
Marijampolė	+20,120.83	+7.74
Panevėžys	+10,581.12	+2.47
Šiauliai	+30,515.29	+6.50
Tauragė	+24,918.24	+12.65
Telšiai	+18,379.67	+9.94
Utena	–20,362.63	-7.55
Vilnius	–18,445.89	-5.60

During the analysed period, the largest decreases in meadow and natural pasture areas were recorded in Šiauliai, Marijampolė, Telšiai, and Tauragė counties (Table 6). Moderate declines were observed in Alytus, Panevėžys, and Kaunas counties, while the smallest changes were recorded in Klaipėda and Vilnius regions.

An exceptional case is Utena county, where meadow and natural pasture areas remained relatively stable (367.65 ha or 0.59%). This suggests a degree of regional stability in land use, potentially related to lower farming intensity, a higher proportion of natural areas, and limited opportunities for the development of intensive crop production.



These trends indicate a long-term shift towards a more intensive land-use model which, while enhancing agricultural productivity, poses challenges for sustainable landscape management.

To strengthen the interpretation of the results, it is important to place the observed land-use changes in Lithuania within the broader European context. The results of this study are consistent with broader European evidence on long-term agricultural land-use change. The observed increase in arable land and the concurrent decline of meadows and natural pastures in Lithuania align with well-documented patterns of agricultural intensification across Europe, where farm specialization and policy-driven restructuring have led to the simplification of agricultural landscapes and the reduction of meadows and natural pastures (Stoate et al., 2009; Pe'er & Dicks, 2014). Similar processes have been identified in Central and Eastern Europe, where changes in post-accession agricultural frameworks and rural development policies have accelerated the conversion of meadows and natural pastures into arable land and reinforced production-oriented farming systems (Pe'er & Dicks, 2014).

At the same time, European studies highlight regional heterogeneity in meadows and natural pastures dynamics. While intensification dominates in many productive agricultural regions, Western Europe increasingly experiences meadows and natural pastures loss driven not only by intensification but also by land abandonment and rewilding processes, leading to divergent landscape trajectories (Plieninger et al., 2014). In contrast, Lithuania's land-use change is primarily

characterized by active agricultural restructuring and expansion of arable farming rather than large-scale abandonment, reflecting its relatively high agricultural suitability and post-Soviet land reform legacy.

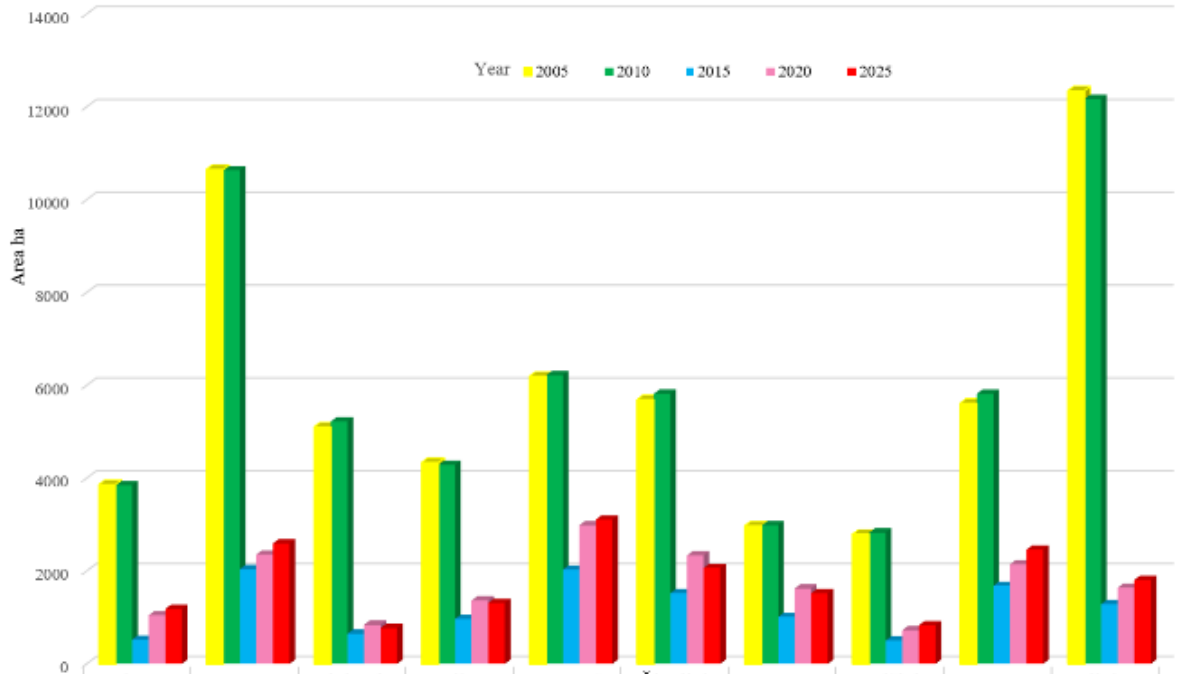
Vilnius	−9,084.92	−12.78

The analysis of *orchard* area changes during 2005–2025 revealed a significant decline in orchard areas across all Lithuanian counties, with the most pronounced decrease occurring between 2005 and 2015 (Figure 7).



The most pronounced decline in orchard areas, both in absolute and relative terms, was observed in Vilnius county, where orchard land decreased by 10,537.58 ha (85.34%) over the 2005–2025 period. Similarly strong reductions were recorded in Kaunas (8,057.23 ha; 75.64%) and Klaipėda (4,333.84 ha; 84.93%) counties, indicating a substantial long-term contraction of orchard systems in both urban and agricultural regions. In contrast, the smallest absolute reductions were identified in Tauragė and Telšiai counties, where orchard areas declined by 1,453.27 ha and 1,959.45 ha, respectively. When expressed in relative terms, the lowest percentage losses were observed in Tauragė (48.85%) and Panevėžys (49.80%) counties suggesting comparatively higher persistence of orchard land in these regions (Table 7).

The decline of orchards observed in Lithuania is also consistent with broader European trends, where traditional orchard systems have been gradually disappearing due to agricultural modernization and structural transformation of rural economies (Demestihas et al., 2017). However, in some Mediterranean regions, orchards remain more stable due to specialization in high-value perennial production systems, indicating important spatial differences in land-use trajectories across Europe.

The results indicate a pronounced long-term restructuring of Lithuania's agricultural land-use system over the 2005–2025 period, characterized by increasing agricultural intensification and a progressive simplification of land-use patterns.

These findings highlight the need for integrated land-use planning strategies that balance agricultural productivity with ecological sustainability and the preservation of semi-natural and traditional landscape elements.

Causes of Land-Use Change

Land-use change in Lithuania is shaped by a complex interplay of economic, policy-related, technological, and socio-environmental factors, rather than by a single dominant driver. A key mechanism underlying observed transformations is the increasing economic efficiency and profitability of crop production, particularly within cereal-oriented farming systems. This has encouraged a gradual reallocation of land from less productive uses toward arable farming, especially in areas with favourable agronomic conditions.

Policy frameworks have played a significant facilitating role in this process. The Common Agricultural Policy (CAP) has indirectly promoted land-use restructuring through support mechanisms that prioritize productivity and investment in agricultural modernization. These incentives, combined with advances in mechanisation and farming technologies, have enabled the cultivation of land previously considered marginal or less suitable for intensive agriculture.

At the same time, structural changes in the livestock sector have reduced the demand for permanent grassland. The long-term decline in animal husbandry has weakened the economic function of meadows and pastures, accelerating their gradual conversion into arable land and contributing to broader simplification of agricultural landscapes.

Urban expansion represents an additional pressure factor, especially in peri-urban zones surrounding major cities and regional centres. In these areas, agricultural land is increasingly converted into residential, infrastructural, or commercial uses, thereby reducing the continuity of traditional agricultural landscapes.

The decline of meadows and natural pastures is closely linked to these combined structural changes. It reflects a broader shift from extensive, livestock-based systems toward more intensive crop production, supported by economic and policy incentives. As

grassland systems lose their economic relevance, they are progressively replaced or abandoned, contributing to habitat loss and reduced landscape diversity.

Similarly, the reduction in orchard areas is associated with long-term restructuring of rural economies and demographic change. Horticultural systems have become increasingly vulnerable due to high labour requirements, production costs, and market competition, which often makes them less economically viable compared to arable farming. As a result, many orchards are converted to alternative land uses, a process further reinforced by rural depopulation, agricultural specialization, and shifting consumption patterns.

Taken together, these processes indicate that land-use change in Lithuania is primarily driven by internal agricultural restructuring rather than by large-scale external abandonment dynamics. The overall trajectory points toward increasing dominance of arable farming, reduced land-use diversity, and progressive simplification of rural landscapes, with important implications for ecological integrity, landscape functionality, and long-term sustainability of agricultural systems.

Conclusions

1. The study demonstrates a pronounced long-term restructuring of agricultural land use in Lithuania, characterized by the growing dominance of arable land and the parallel contraction of meadows, natural pastures, and orchards. These shifts indicate a transition toward a more production-oriented and specialized agricultural system, reflecting broader processes of agricultural intensification and functional simplification of rural land use.
2. Spatial differences across counties reveal a persistent regional differentiation in land-use structure, where areas with more favourable agricultural conditions are increasingly oriented toward intensive arable farming, while less intensive regions retain relatively higher proportions of semi-natural and perennial land-use forms. This spatial pattern highlights the continuing imbalance in agricultural development trajectories within the country.
3. The substantial reduction of meadows and natural pastures has important implications for biodiversity conservation and ecosystem functioning. The loss of these semi-natural habitats reduces landscape heterogeneity, weakens ecological connectivity, and negatively affects species dependent on grassland ecosystems. From a territorial planning perspective, this trend increases the vulnerability of rural landscapes to ecological degradation and limits opportunities for multifunctional land use.
4. The decline of orchards reflects the ongoing marginalization of traditional, low-intensity land-use systems, which historically contributed to landscape diversity and cultural heritage. Their reduction signals not only economic restructuring but also the gradual erosion of structurally diverse agricultural landscapes, which play an important role in maintaining both ecosystem services and local identity.
5. Future research should focus on more detailed spatial modelling of land-use transitions, the integration of socio-economic drivers at farm level, and the assessment of ecosystem service losses associated with the decline of semi-natural land uses. In addition, scenario-based studies would be valuable for evaluating policy options aimed at balancing agricultural productivity with biodiversity conservation and sustainable land management objectives.

MOSS-BASED VERTICAL BARRIERS AS HYBRID INFRASTRUCTURES FOR URBAN PM MONITORING AND MITIGATION

Edgars Karklins

Corresponding author's email: edgars.karklins@lbtu.lv

Abstract
Air pollution remains a major environmental and public health challenge in urban areas, particularly due to fine particulate matter ($PM_{2.5}$), which can penetrate deeply into the respiratory system. According to the World Health Organisation, $PM_{2.5}$ is among the air pollutants with the highest documented impact on human health, especially in urbanised settings. This study evaluated a moss-based vertical barrier as green infrastructure for local mitigation under real outdoor urban conditions. The experimental system consisted of a freestanding moss-covered panel equipped with paired low-cost $PM_{2.5}$ sensors positioned on the street-facing and park-facing sides of the barrier. Monitoring was conducted in Riga, Latvia, from 1 November 2025 to 31 January 2026 under winter conditions characterised by variable wind, temperature, and precipitation. Quantitative interpretation was based on the validated Riga dataset comprising 80,302 observations processed using a 60-minute moving average; the results showed that $PM_{2.5}$ concentrations behind the moss barrier were lower than on the street side in 53.3% of observations. The average relative reduction reached 6.68%, corresponding to an absolute reduction of 1.33 μg m^{-3}. Barrier performance varied with wind direction, indicating the importance of atmospheric flow conditions for local mitigation efficiency. The findings demonstrate that moss-based vertical barriers can provide modest but measurable $PM_{2.5}$ attenuation while also functioning as decentralised environmental monitoring units within hybrid urban green infrastructure systems.
Keywords: moss wall, $PM_{2.5}$, urban air pollution, green infrastructure, environmental monitoring.

Introduction

Air pollution remains one of the most significant environmental challenges in urban areas and is currently associated with millions of premature deaths annually worldwide. Fine particulate matter ($PM_{2.5}$) is considered particularly harmful because particles smaller than 2.5 μm can penetrate deeply into the respiratory system, enter the bloodstream, and affect multiple organs, including the cardiovascular and nervous systems (World Health Organisation, 2021). According to the World Health Organisation (WHO), $PM_{2.5}$ is among the air pollutants with the highest documented impact on public health, especially in densely populated urban regions where exposure is continuous. Urbanisation intensifies this problem because pollutant emissions from transport, domestic heating, construction, and industrial activities accumulate in areas where atmospheric dispersion is restricted by street canyons and built structures (Anderson et al., 2011; Liang et al., 2021). In Europe, almost all urban populations are exposed to $PM_{2.5}$ concentrations exceeding recommended health guidelines, with particularly elevated values observed in Central and Eastern European cities (European Environment Agency, 2024). In Riga, $PM_{2.5}$ remains one of the dominant air-quality concerns, influenced by traffic emissions, winter heating, and regional transport from industrial and port-related activities. The concentration and movement of $PM_{2.5}$ in urban air depend strongly on meteorological conditions. Wind direction, wind speed, precipitation, humidity, and temperature influence pollutant transport, dilution, and deposition processes (Jing et al., 2020; Yang et al., 2017; Xie et al., 2022). Strong winds usually enhance dispersion, whereas low wind speed and atmospheric stability promote local accumulation. In winter, thermal inversions and reduced vertical mixing often increase $PM_{2.5}$ concentrations in near-ground air layers, making local mitigation particularly relevant in pedestrian environments. As conventional urban air-quality policies often focus on emission reduction at the city scale, increasing attention has been given to local nature-based solutions capable of reducing pollutant exposure at micro-scale locations. Vegetated barriers, green walls, roadside hedges, and other green infrastructure elements may modify local turbulence, intercept airborne particles, and increase deposition onto biological surfaces (Hewitt et al., 2019; Kumar et al., 2019; Medl et al., 2017). Vertical vegetation systems are especially relevant where horizontal space for planting is limited. Among biological materials, mosses have advantages for atmospheric applications because they lack a cuticle, possess high surface roughness, and absorb airborne particles directly through their surface. Mosses are widely used in biomonitoring studies because they accumulate particulate and trace-element pollution efficiently (Capotorti et al., 2013; Giordano et al., 2005). Their ability to function as passive particulate collectors suggests additional potential for engineered mitigation systems integrated into urban infrastructure. Previous studies have demonstrated that vegetation can reduce local particulate concentrations, but most experiments have focused either on laboratory conditions or on conventional vascular plants (Weber et al., 2014; Ren et al., 2023). Evidence for moss-based vertical barriers under outdoor winter conditions in temperate European cities remains limited. In addition, the integration of biological filtration surfaces with low-cost digital PM sensors introduces new possibilities for digital infrastructures capable of both mitigation and continuous environmental observation. This study evaluates a freestanding moss-based vertical barrier installed in *Viesturdārzs,* Riga (Latvia) under winter outdoor conditions. The study aimed to assess $PM_{2.5}$ concentration differences across the barrier, determine

the influence of wind direction on local barrier performance, and evaluate the suitability of moss-based systems as decentralised urban monitoring elements. Quantitative interpretation was based on the validated primary dataset.

Materials and Methods

The study was conducted in Riga, in the urban green area of *Viesturdārzs*, where a freestanding moss-based vertical barrier was installed as an experimental nature-based infrastructure for particulate matter monitoring and local mitigation. The site is located in a dense urban environment influenced by road traffic, nearby transport corridors, and atmospheric transport from port-related industrial activities situated in the northern part of the city. The barrier was positioned perpendicular to the dominant air flow to intercept airborne particles transported between the street and park zones. The experimental system consisted of autonomous vertical panels covered with moss vegetation and equipped with paired low-cost $PM_{2.5}$ sensors installed on both sides of the structure (Figure 1).

Figure 1

Moss barrier placed in Riga, Viesturdarzs

The moss panels consisted of vertically mounted modular frames supporting moss-covered substrate layers designed to maximise surface roughness and air contact. The structure allowed passive airflow through the vegetation layer, facilitating particle interception and deposition. The $PM_{2.5}$ measurements were obtained using calibrated low-cost optical sensors (Pollutrack system), operating with a temporal resolution of 1-minute intervals. One sensor was positioned on the street-facing side to measure incoming particulate concentration, while the second sensor was placed on the park-facing side to detect concentration after air passage across the barrier (Figure 2).

Sensor performance was monitored throughout the study period, and maintenance procedures included regular visual inspection and cleaning of sensor inlets to prevent obstruction by moisture or particulate accumulation. Sensor malfunction was identified based on abnormal readings, including persistent extreme values, lack of temporal variability, or unrealistic divergence between paired sensors. Data from sensors exhibiting such anomalies were excluded from further analysis.

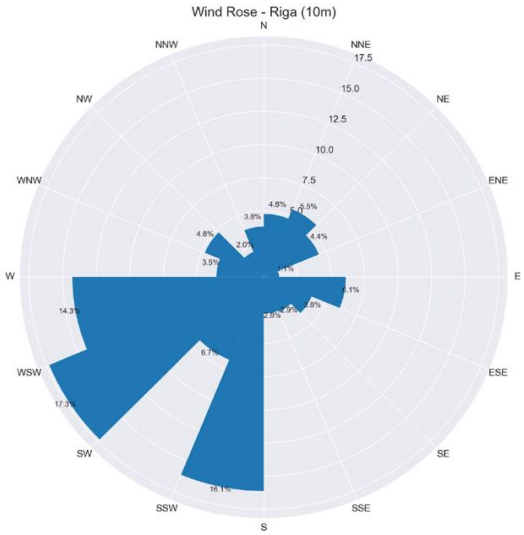
Figure 2

Close-up of a sensor placed on the barrier

Two installations were operated during the study period: medium (sized 3x5m) and large (sized 3x7m). However, quantitative interpretation in this study was based only on the medium installation because the Riga large display park-side sensor produced anomalously high values that indicated probable clogging or sensor malfunction. Therefore, the large display data was excluded from efficiency calculations. Monitoring was performed continuously from 1 November 2025 to 31 January 2026 under winter outdoor conditions characterised by variable temperature, humidity, precipitation, and wind regimes. The validated dataset of 80,302 observations was obtained after applying quality-control procedures, including removal of missing values, elimination of outliers exceeding physically plausible $PM_{2.5}$ concentration ranges, and exclusion of data segments affected by identified sensor malfunction. Data smoothing using a 60-minute moving average was applied to reduce short-term fluctuations and ensure comparability between measurement points. Barrier efficiency was evaluated using two indicators: absolute reduction and relative reduction. Absolute reduction was calculated as the mean difference between street-side and park-side $PM_{2.5}$ concentrations:

Absolute reduction = Mean (Street − Park)

Relative reduction was calculated as:



Relative reduction (%) = 100 × Mean (Street − Park) / Mean (Street).

Negative differences indicated lower particulate concentration behind the moss barrier and were interpreted as local attenuation effects. Meteorological influence was assessed using ERA5 atmospheric data. Particular attention was given to wind direction (Figure 3) because barrier performance depends strongly on airflow orientation.

Westerly winds (250°–290°) were considered the main transport direction from the street towards the park,

while easterly winds (70°–110°) represented the opposite flow configuration. Wind-direction analysis was used to interpret changes in barrier performance under different atmospheric transport conditions.

Figure 3
Wind rose for Riga during the monitoring period from 1 November 2025 to 31 January 2026

A limitation of the study is the reliance on low-cost sensors, which may introduce measurement uncertainty under high humidity and winter conditions. However, paired sensor configuration and data validation procedures were applied to minimise this effect.

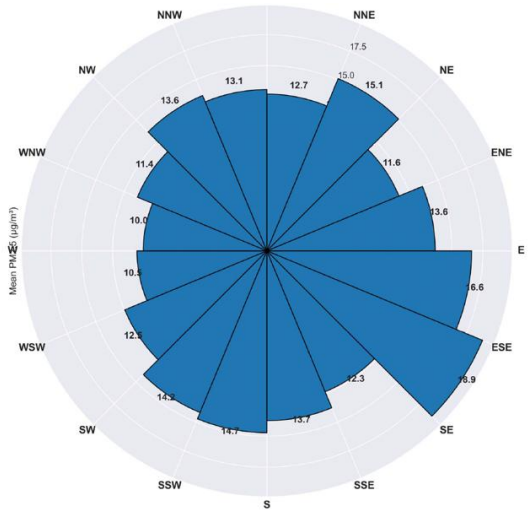
Results and Discussion

The quantitative analysis of the validated medium panel display installation was based on 80,302 $PM_{2.5}$ observations collected during the monitoring period from 1 November 2025 to 31 January 2026. Comparison of concentrations measured on both sides of the moss barrier showed measurable spatial differences between the street-facing and park-facing sensors. In 42,780 observations (53.3%), $PM_{2.5}$ concentration on the park side was lower than on the street side, whereas in 37,522 observations (46.7%), the opposite relationship was observed. This distribution indicates a slight predominance of lower particulate concentrations behind the moss barrier under outdoor urban winter conditions.

For observations where $PM_{2.5}$ concentration behind the barrier was lower than on the street side; the mean relative reduction reached 6.68%, corresponding to an absolute reduction of 1.33 μg m^{-3}. To evaluate whether the observed differences between street-side and park-side $PM_{2.5}$ concentrations were statistically significant, paired comparison analysis was performed.

The mean difference between paired observations was calculated, and variability was assessed using standard deviation. Although the reduction effect was modest, the consistent predominance of lower concentrations behind the barrier suggests that the observed attenuation effect is unlikely to be solely the result of random variation. Future analysis should include formal hypothesis testing (e.g., paired t-test) to further quantify statistical significance.

Table 1
Validated $PM_{2.5}$ reduction results for the Riga moss barrier installation



Label	Value
Observations	80,302
Park < Street	53.3%
Relative reduction	6.68%
Absolute reduction	1.33 μg m^{-3}

Across the full monitoring period, the reduction effect remained modest but occurred more frequently than concentration increases, demonstrating that the moss-covered surface contributed to local particulate attenuation under real environmental exposure. The standard deviation reported in the dataset indicates considerable temporal variability, suggesting that barrier performance changed continuously according to meteorological conditions and local emission dynamics. Although the observed reduction values (6.68% and 1.33 μg m^{-3}) may appear modest, they are environmentally relevant at the micro-scale level, particularly in pedestrian zones where even small reductions in $PM_{2.5}$ exposure can contribute to improved air quality and reduced health risks. Compared to controlled laboratory experiments, the lower efficiency observed in this study reflects the complexity of real urban environments, where turbulence, variable emission sources, and meteorological conditions continuously influence pollutant dispersion and deposition processes. Similar variability in vegetation-based mitigation performance under outdoor conditions has been reported in previous studies (Hewitt et al., 2019; Kumar et al., 2019), confirming that nature-based solutions function as complementary rather than primary filtration systems.

Mean $PM_{2.5}$ concentrations varied considerably according to wind direction during the study period (Figure 4). The highest concentrations were recorded under southeastern and eastern airflows, with maximum values observed for SE (18.9 μg m^{-3}), ESE (16.6 μg m^{-3}), and NE (15.1 μg m^{-3}) directions. In contrast, lower $PM_{2.5}$ concentrations were associated with western sectors, particularly W (10.0 μg m^{-3}) and WNW (11.4 μg m^{-3}). Overall, winds from the east to southeast sector were associated with higher particulate matter loads than winds from the west, indicating a clear directional influence on local $PM_{2.5}$ distribution. For the dominant wind sectors during the monitoring period, concentrations generally ranged between 12.5 and 15 μg/m^3, reflecting a persistent background influence of surrounding urban emission sources. These results suggest that air masses arriving

from eastern sectors transport higher pollutant loads to the site, whereas westerly winds favour stronger atmospheric dispersion and lower $PM_{2.5}$ accumulation.

Figure 4
Distribution of $PM_{2.5}$ pollution depending on wind direction

Furthermore, wind direction had a clear influence on barrier behaviour. Under westerly winds (250°–290°), when polluted air moved from the street towards the park through the barrier, 5,236 valid observations were recorded. In this configuration, the average reduction reached 1.10%, corresponding to an absolute difference of 0.14 µg m^{-3}. Under easterly winds (70°–110°), 7,598 observations were analysed, and the average reduction increased to 2.65%, with an absolute reduction of 0.78 µg m^{-3}. The stronger attenuation observed during easterly flows may be associated with lower wind velocity and reduced atmospheric dilution, which increases particle residence time near the moss surface. The observed influence of wind direction highlights the importance of airflow alignment relative to barrier orientation. Under favourable transport conditions, the moss surface acts as a passive deposition interface, whereas under opposing or turbulent flow conditions, the mitigation effect is reduced or reversed. The measured reduction values are lower than efficiencies reported in some controlled laboratory experiments, which is expected because outdoor urban conditions introduce strong variability through turbulence, precipitation, humidity fluctuations, and changing emission sources. In real environments, moss barriers act not as closed filtration systems but as passive deposition surfaces that locally modify air movement and increase particle capture potential. Data from the second installation (large display) were excluded from quantitative interpretation due to almost all observations showing unrealistically high $PM_{2.5}$ concentrations on the park side, with an average calculated efficiency exceeding 250%, indicating probable sensor contamination or obstruction. This confirms that sensor maintenance and quality control remain critical when green infrastructures are used for continuous environmental monitoring. Overall, the validated results indicate that moss-based vertical barriers can provide modest but measurable local $PM_{2.5}$ attenuation while simultaneously functioning as decentralised monitoring elements within urban green infrastructure systems.

Conclusions

1. The validated moss-based vertical barrier installation showed measurable $PM_{2.5}$ attenuation under outdoor winter urban conditions, with lower concentrations behind the barrier recorded in 53.3% of observations.
2. The average relative reduction reached 6.68%, corresponding to an absolute reduction of 1.33 µg m^{-3}, indicating a modest but consistent local mitigation effect.
3. Wind direction influenced barrier performance, with measurable differences observed under both westerly and easterly atmospheric flow conditions.
4. The results confirm that moss-based vertical barriers can function as passive local biofiltration surfaces while simultaneously serving as decentralised air-quality monitoring elements.
5. Sensor reliability remains a critical factor for green infrastructure, as anomalous measurements from the second installation required exclusion from quantitative interpretation.

VEGETATIVE PROPAGATION OF BRYOPHYTES FOR URBAN DEPLOYMENT AND ECOSYSTEM SERVICES PROVISION

Juta Karklina
Latvia University of Life Sciences and Technology, Latvia
Corresponding author's email: juta.karklina@lbtu.lv

Abstract
Bryophytes, especially mosses, are increasingly recognised as multifunctional components of urban green infrastructure due to their capacity to contribute to ecosystem services such as air quality regulation, noise attenuation, microclimate stabilisation, and mitigation of urban heat island effects. The large-scale application of moss-based solutions, however, is constrained by the limited availability of sustainably produced moss biomass and by species-specific differences in cultivation requirements. This study presents a controlled, non-sterile vegetative propagation approach for selected moss species commonly associated with ecosystem service provision in urban environments. Four species—*Hypnum cupressiforme, Pleurozium schreberi, Plagiomnium affine,* and *Dicranum scoparium*—were propagated from vegetative fragments on hemp fibre substrates under controlled temperature (15–21 °C), relative humidity (60–80%), and light intensity (1000–2000 lux). Surface coverage, species vitality, and susceptibility to microbial contamination were monitored over a four-month cultivation period. The results demonstrate clear interspecific differences in growth strategies and resilience under controlled conditions. *Plagiomnium affine* exhibited rapid initial growth but limited long-term stability, while *Hypnum cupressiforme* showed slower establishment combined with high robustness and regenerative capacity. *Pleurozium schreberi* and *Dicranum scoparium* required higher initial planting densities to achieve stable coverage and were more sensitive to cultivation stress. These findings highlight the importance of species-specific propagation strategies when cultivating mosses intended for ecosystem service provision in urban environments. The study provides a practical knowledge base for sustainable moss biomass production as a prerequisite for future ecological and functional applications.
Keywords: bryophytes, moss cultivation, moss propagation, ecosystem services, biomass production.

Introduction

Ecosystem services refer to the benefits that humans derive from ecosystems and are commonly classified into four categories: provisioning, supporting, cultural, and regulating (Reid, 2005; Gómez-Baggethun et al., 2013). Regulating ecosystem services include ecological functions that moderate environmental conditions, such as air purification, temperature regulation, stormwater control, and noise attenuation, which are particularly important in densely urbanised areas where natural buffering capacity is reduced (Bolund & Hunhammar, 1999; Zulian et al., 2017).

Bryophytes and mosses in particular are increasingly recognised as functional components of urban green infrastructure due to their capacity to provide regulating ecosystem services under limited substrate conditions (Glime, 2021; Perini et al., 2020). Their poikilohydric physiology, lack of cuticle, and high surface-to-volume ratio allow direct exchange with atmospheric moisture and pollutants, making them particularly suitable for urban environmental applications (Perini et al., 2020; Chaudhuri & Roy, 2024; Garabito et al., 2017). The role of mosses in urban air pollution mitigation has gained increasing attention in recent years. For example, moss-based filtration systems have demonstrated the ability to capture PM and improve local environmental quality in engineered urban installations (Biloshchytskyi et al., 2023; Kārkliņa et al., 2024; Perini et al., 2025). Mosses are also widely recognised as atmospheric bioindicators because they accumulate airborne pollutants directly through their surface tissues and reflect local deposition patterns over time (Rühling & Tyler, 1968; Lazo et al., 2022; Chaudhuri & Roy, 2024). Urban deployment of mosses requires reliable biomass production since direct harvesting from natural habitats cannot support large-scale implementation and creates ecological pressure on natural ecosystems. Therefore, controlled cultivation becomes essential and can be achieved using several propagation approaches depending on the intended application and available infrastructure. In laboratory conditions, sterile in vitro propagation is frequently employed, enabling precise control over growth media, nutrient supply, and contamination levels. This method enables the rapid multiplication of moss biomass but requires specialised laboratory facilities and species-specific optimisation of culture media (Ćosić et al., 2025; Heck et al., 2021). Alternatively, non-sterile vegetative propagation represents a more practical approach for large-scale biomass production. In this method, moss fragments are cultivated on suitable substrates under controlled environmental conditions, including regulated temperature, humidity, and light intensity. Vegetative propagation utilises the natural regenerative capacity of bryophyte tissues, allowing new shoots to develop from fragmented plant material (Liu et al., 2021; Zechmeister et al., 2023).

Previous studies have demonstrated that the regeneration capacity of bryophyte species differs substantially, influencing cultivation efficiency and the long-term stability of propagated biomass. Therefore, selecting the appropriate species and cultivating under suitable conditions is essential for the successful application of moss in environmental settings (Morales-Sánchez et al., 2022; Haughian & Lundholm, 2024). Mosses possess a high regenerative ability due to the presence of meristematic cells distributed along their gametophyte tissues, allowing regeneration even from small shoot fragments, which makes vegetative propagation particularly effective compared to many vascular plant systems (Glime, 2021). Non-sterile

controlled propagation offers a more accessible alternative for producing moss biomass for urban green infrastructure applications (Zechmeister et al., 2023; Liu et al., 2021). Species differ substantially in regeneration speed, tolerance to moisture fluctuations, and resistance to microbial contamination. These interspecific differences directly influence cultivation success and later performance under urban environmental stress, particularly when mosses are intended for vertical systems, roofs, or linear barriers exposed to fluctuating temperature and hydration cycles (Haughian & Lundholm, 2024; Morales-Sánchez et al., 2022). This study aimed to evaluate vegetative propagation performance of four moss species under controlled non-sterile conditions and to identify cultivation parameters relevant for future ecosystem service applications in urban environments.

Materials and Methods

Four moss species were selected for vegetative propagation: *Hypnum cupressiforme, Pleurozium schreberi, Plagiomnium affine,* and *Dicranum scoparium.* Species selection was based on previous experimental observations showing their suitability for urban ecological applications, their morphological diversity, and their resilience under controlled cultivation conditions (Kārkliņa et al., 2024; Perini et al., 2020). Moss material was collected manually from forest habitats in accordance with sustainable biomass collection principles. Only green photosynthetically active segments were retained, while brown basal tissue and organic impurities were removed manually before cultivation. The prepared material was distributed manually onto pre-wetted hemp fibre mats (60 × 60 × 0.4 cm), ensuring near-complete (90%) initial substrate coverage. Lower initial densities had previously resulted in desiccation and reduced vitality. Mosses were placed on the substrate as monocultures – one species per hemp mat. This substrate was selected because of its water retention properties and biodegradability, which support moss establishment under controlled humidity conditions (Addo-Bankas et al., 2024). Cultivation took place in a climate-controlled indoor facility under non-sterile conditions (Figure 1). Environmental parameters were maintained as follows: temperature, 15–21 °C; relative humidity, 60–80%; light intensity, 1102–2573 lux; and photoperiod, 8 h light/16 h dark. These conditions were selected based on previous studies demonstrating that temperature, humidity, and irrigation regime strongly influence moss viability in indoor systems (Zechmeister et al., 2023; Perini et al., 2025). Mosses were irrigated three times daily using reverse osmosis water. Once per week, a modified Knop nutrient solution was applied at ¼ strength, consisting of calcium nitrate (0.25 g L^{-1}), potassium nitrate (0.06 g L^{-1}), potassium phosphate (0.06 g L^{-1}), and magnesium sulfate (0.06 g L^{-1}), supplemented with ammonium nitrate at a concentration of 0.04–0.08 g L^{-1} (equivalent to 0.5–1 mM). Approximately 100 mL of solution was applied per cultivation unit following nutrient recommendations developed for bryophyte cultivation (Heck et al., 2021; Ćosić et al., 2025). Growth was monitored visually over four months by assessing surface coverage, color stability, new shoot formation, and symptoms of contamination. Surface coverage was visually assessed at regular intervals during the cultivation period through repeated comparative observations of each cultivation unit. Surface coverage was expressed as the percentage of substrate area occupied by living moss biomass, based on repeated visual estimation under standardised lighting conditions. In addition to coverage, qualitative indicators of vitality were assessed, including colour intensity and shoot density. Colour intensity was evaluated using a three-level visual scale (green – indicating high vitality; pale green – indicating moderate vitality; yellow/brown – indicating reduced vitality or stress). Shoot density was assessed comparatively by observing the relative compactness of regenerated shoots across the substrate surface (low, medium, high density). All visual assessments were conducted by the same observer at regular intervals throughout the four-month cultivation period to ensure consistency. Observations were performed after irrigation cycles, when surface moisture conditions were stable, in order to minimise variability caused by temporary desiccation. To ensure comparability between species, all observations were performed under identical lighting conditions and after irrigation cycles had stabilised surface moisture conditions. The obtained coverage values were subsequently used for descriptive statistical analysis and interspecific comparison.

During cultivation, fungal contamination was treated using Hydrogen peroxide, which slowed the spread of fungi, but concentrations above 1.25% caused visible chlorosis, indicating the limited applicability of chemical suppression under long-term cultivation.

After completion of the four-month controlled indoor cultivation phase, the moss mats were relocated to outdoor conditions to undergo winter exposure. The cultivated material remained outdoors for six months before subsequent visual assessment.

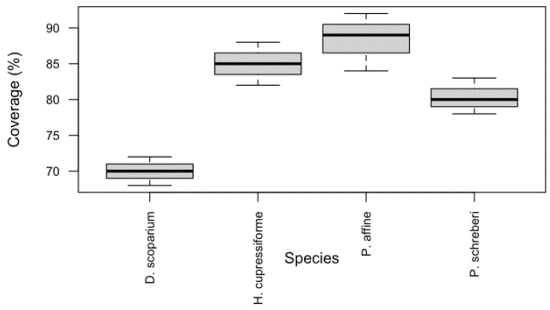
Statistical analysis of surface coverage data was performed using R statistical software. Analysis of variance (ANOVA) and Tukey HSD post hoc comparisons were applied to evaluate interspecific differences in coverage values. Descriptive statistics were calculated to determine mean values, standard deviation, minimum, and maximum coverage. Graphical visualisation of results was prepared using boxplot and barplot functions in RStudio.

Results and Discussion

The four species showed clear differences in establishment dynamics under identical cultivation conditions. *Plagiomnium affine* exhibited the most rapid early development, reaching approximately 2 cm shoot elongation within two to three months. However, vitality declined after the third month, particularly under monoculture conditions, while a mix of all moss

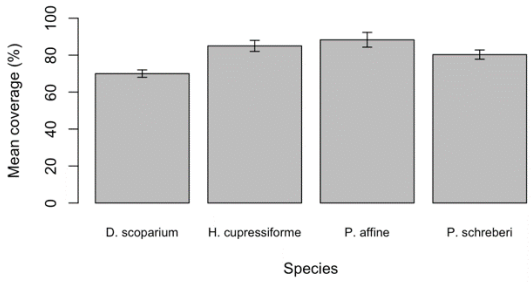
species was stronger. This suggests a high colonisation potential, combined with limited long-term stability under continuous high humidity, which corresponds with the fast colonisation strategies described for bryophyte growth under favourable moisture conditions (Glime, 2021; Liu et al., 2021). By contrast, *Hypnum cupressiforme* showed slower initial growth but the highest resilience during the full cultivation period. It regenerated effectively in low-density areas and in zones affected by microbial contamination, indicating strong tolerance to cultivation stress and stable persistence under fluctuating humidity conditions (Morales-Sánchez et al., 2022). *Pleurozium schreberi* required higher planting density to achieve stable coverage, while *Dicranum scoparium* showed the greatest sensitivity to low density and contamination. Low-density cultures of *D. scoparium* frequently developed chlorosis and tissue loss. After four months, most cultivation units exceeded 80% surface coverage, confirming the practical suitability of non-sterile vegetative propagation for biomass production.

Figure 1
Moss cultivation within a controlled environment after four months



Analysis of variance (ANOVA) was applied to determine whether the observed differences in surface coverage among cultivated moss species were statistically significant, since species-specific variation was expected to influence cultivation performance under identical environmental conditions.

ANOVA revealed statistically significant differences in surface coverage among the cultivated moss species ($F = 21.44$, $p = 0.000352$), indicating species-specific variation in establishment performance under controlled cultivation conditions.



Plagiomnium affine demonstrated the highest median coverage, whereas *Dicranum scoparium* had the lowest (Figure 2). Post hoc Tukey HSD analysis further demonstrated that *Dicranum scoparium* differed significantly from all other species in surface coverage. Significant differences were observed between Dicranum scoparium and *Hypnum cupressiforme* ($p = 0.0012$), *Plagiomnium affine* ($p = 0.0003$), and *Pleurozium schreberi* ($p = 0.0121$). In addition, *Pleurozium schreberi* differed significantly from *Plagiomnium affine* ($p = 0.0448$).

Figure 2
Surface coverage differences among cultivated moss species under controlled propagation conditions

The mean surface coverage values with standard deviations for the cultivated moss species after four months of controlled propagation (Figure 3) indicate that *Plagiomnium affine* achieved the highest mean coverage (88.3 ± 4.0%), followed by *Hypnum cupressiforme* (85.0 ± 3.0%). In contrast, *Dicranum scoparium* showed the lowest mean coverage (70.0 ± 2.0%).

Figure 3
Mean surface coverage and standard deviation among cultivated moss species under controlled propagation conditions

The statistical differences observed in surface coverage corresponded closely with visual cultivation dynamics recorded during the monitoring period. Species showing higher mean coverage values also demonstrated more homogeneous shoot expansion and lower susceptibility to local tissue degradation. In contrast, lower coverage values were associated with delayed lateral expansion, reduced density of regenerated shoots, and greater sensitivity to contamination episodes. Similar growth performance has been reported in other controlled moss cultivation studies where vegetative fragments were used for biomass multiplication (Liu et al., 2021; Zechmeister et al., 2023).

During the cultivation span, microbial contamination remained the primary limitation to cultivation. Comparable contamination challenges are described in non-axenic bryophyte production systems (Ćosić et al., 2025). The observed differences correspond to ecological growth strategies described by Grime (2001), where rapidly colonising species show weaker stress tolerance, while slower-growing species provide greater cultivation stability.

After four months of controlled indoor cultivation, the moss mats were transferred to outdoor conditions to assess their ability to maintain vitality beyond the controlled propagation phase during winter exposure. Following six months under external environmental conditions, the cultivated moss biomass still showed visible signs of viability, including preserved green pigmentation and structural integrity in most cultivation units (Figure 4).

Finally, findings confirm that reliable biomass production remains a necessary precondition for broader investigation of moss-based ecosystem service applications in urban environments.

Since bryophytes are increasingly considered as functional elements of green infrastructure, the availability of stable cultivated material is essential for subsequent experimental studies addressing PM retention, microclimate regulation, moisture buffering, and other regulating ecosystem services.

Figure 4

Cultivated mosses in an outdoor environment

The present cultivation experiment, therefore, represents an initial practical stage within a broader research direction focused on evaluating moss species not only for propagation efficiency but also for their environmental performance under urban conditions.

Conclusions

1. Non-sterile vegetative propagation under controlled indoor conditions enabled the successful establishment of all four cultivated moss species on hemp fibre substrate.
2. Significant interspecific differences in surface coverage were identified, confirming that moss species differ in regeneration performance under identical cultivation conditions.
3. *Plagiomnium affine* and *Hypnum cupressiforme* demonstrated the highest surface coverage and the most stable establishment during the four-month cultivation period. *Dicranum scoparium* showed the lowest surface coverage and the highest sensitivity to cultivation conditions, indicating lower suitability for rapid biomass production.
4. Outdoor exposure after indoor cultivation confirmed that propagated moss mats retained viability under winter conditions, supporting their potential for further application in urban green infrastructure systems.

Acknowledgements

The authors acknowledge the support of the Bulduri Biotechnology Centre, where the initial indoor cultivation experiments were carried out. Scientific guidance for the study was provided by Dr. biol. Līga Strazdiņa from the University of Latvia Botanical Garden. The technical implementation of the cultivation protocol was performed by Roberts Krūmiņš (Bulduri Biotechnology Centre researcher), with additional contributions from Edgars Kārkliņš (PhD researcher at Latvia University of Life Sciences and Technologies). After the indoor cultivation phase, the moss material was transferred to two facilities for further maintenance and continuation of the experimental cultivation: Norupe Tree Nursery (‘Rigas Meži’ facility) and the University of Latvia Botanical Garden. This research was funded by a MikroTik donation administered through the University of Latvia Foundation and by financial support from Rīgas Meži. The study contributes to ongoing doctoral research in environmental engineering conducted by Juta Kārkliņa at Latvia University of Life Sciences and Technologies.

IRRIGATION PRIORITIZATION MODEL FOR DROUGHT RESILIENCE: CROP RANKING AND WATER SAVING SCENARIOS

***Vilda Grybauskiene[1], Gitana Vyciene[1], Inga Grinfelde[1], Ulaş Şenyiğit[2]**

Abstract
Drought-induced water scarcity increasingly constrains irrigation planning and is expected to intensify under climate change. Under limited water availability, efficient allocation of irrigation water is essential to minimize yield losses and improve water-use efficiency. This study develops a decision-support model that ranks crops during drought conditions by integrating crop water requirements, yield response to deficit irrigation, and economic valuation of production. The model is applied to the Ararat region (Armenia), a drought-prone area with irrigation-dependent agriculture. Results indicate that moderate irrigation restriction can reduce seasonal water use by 28–45% while maintaining a substantial share of crop yield. Under severe drought conditions, reallocating water from low-priority crops to higher-value crops reduces total economic losses. The proposed prioritization index (EUR m^{-3}) provides a transparent basis for ranking crops according to the economic value of irrigation water. Results further show that tomato generates the highest economic return per unit of irrigation water, while potato exhibits the lowest priority. This index-based approach is applicable to other water-scarce agricultural regions seeking transparent allocation tools. The framework is designed as a simplified, scenario-based tool intended for comparative analysis under data-limited conditions. It supports regional drought management by enabling systematic evaluation of irrigation allocation strategies.
Keywords: irrigation, droughts, crop water requirements, water allocation strategies.

Introduction

Drought frequency and intensity have increased in many semi-arid and continental regions, intensifying seasonal water shortages and placing irrigation-dependent agriculture under increasing pressure. Global climate assessments indicate that rising temperatures, increased evapotranspiration and higher precipitation variability are expected to aggravate water scarcity in many agricultural regions (Intergovernmental Panel on Climate Change, 2021).

Climate projections for the South Caucasus region suggest a continued warming trend and increasing hydrological variability, which may significantly intensify agricultural water deficits and irrigation demand (United Nations Development Programme, 2011). Under such conditions, irrigation management gradually shifts from maximizing crop production under sufficient water supply to optimizing allocation under water scarcity.

Agriculture in Armenia remains strongly dependent on irrigation, particularly in lowland agricultural zones such as the Ararat Valley. Approximately one quarter of the country's arable land is irrigated, and crop productivity in these areas relies heavily on stable seasonal irrigation supply (Food and Agriculture Organization, 2016; World Bank, 2018; Yu et al., 2014). During drought years, available irrigation water often becomes insufficient to meet full crop water requirements. In many irrigation systems, water reductions are applied uniformly across crops in order to distribute shortages. However, such approaches may lead to inefficient allocation of scarce water resources and disproportionate economic losses.

Several regional studies highlight the vulnerability of Armenia's irrigated agriculture to climate-driven water scarcity and increasing irrigation demand. For example, Aram Melkonyan and co-authors show that Armenia's agricultural sector is highly sensitive to climate change due to increasing temperatures, declining precipitation and rising evapotranspiration, which together intensify irrigation water shortages and threaten crop productivity (Melkonyan et al., 2015). Their modelling results indicate that irrigation demand may increase substantially in major agricultural regions under future climate scenarios.

Complementary hydrogeological research conducted in the Ararat Valley demonstrates that groundwater resources supporting irrigation systems are under increasing pressure from agricultural water withdrawals and reduced recharge rates. Environmental tracer analysis confirms that the valley's aquifers still receive modern recharge but remain vulnerable to over-exploitation due to intensive irrigation and expanding agricultural water demand (Schubert et al., 2021). Together, these studies emphasize that improving irrigation efficiency and developing economically informed water allocation mechanisms are critical for maintaining agricultural productivity under increasing water scarcity in Armenia.

Economic theory suggests that scarce water resources should be allocated according to their marginal productivity, prioritizing uses that generate the highest economic return per unit of water (Young, 2005; Ward & Michelsen, 2002). In irrigated agriculture, the economic value of irrigation water can be expressed as the change in agricultural output resulting from incremental changes in water supply. When water availability declines, crops generating lower economic return per cubic metre of water should be reduced first in order to minimize total economic losses.

Agronomic research provides the methodological basis for linking irrigation water deficits with crop yield response. A widely used framework is the FAO yield–water production function, which describes the

relationship between relative yield reduction and relative evapotranspiration deficit (Doorenbos & Kassam, 1979). The model assumes that yield losses are proportional to evapotranspiration deficits, enabling estimation of crop productivity under different irrigation regimes.

Later developments expanded this framework and produced practical tools for estimating crop yield under deficit irrigation conditions (Steduto et al., 2012). These models form the basis of modern crop–water productivity analysis and irrigation planning tools such as AquaCrop.

Deficit irrigation strategies demonstrate that controlled reductions in irrigation can significantly reduce water consumption while preserving a substantial share of crop yield, depending on crop sensitivity and the timing of water stress during the growing season (Fereres & Soriano, 2007). In water – limited environments, irrigation management, therefore, increasingly focuses on maximizing crop production per unit of water rather than per unit of land (Molden et al., 2010).

Despite the availability of hydrological and agronomic models capable of estimating crop water requirements and yield response, practical decision-support frameworks that translate irrigation shortages into crop-level prioritization remain limited at regional scale. Existing drought management strategies in Armenia mainly focus on infrastructure development and water supply stabilization rather than on operational allocation tools capable of guiding crop prioritization during seasonal shortages (United Nations Development Programme, 2015; World Bank, 2018).

Therefore, a transparent and economically grounded framework is needed to support irrigation allocation decisions during drought conditions. By integrating irrigation volumes, crop yield response functions and market valuation of agricultural production, such a framework can enable systematic ranking of crops under progressive irrigation restrictions and support economically efficient water allocation during water scarcity events.

The objective of this study is to develop and apply an irrigation prioritization index that combines agronomic yield response with economic valuation of crop production. The proposed framework is designed to support crop-level ranking under different irrigation reduction scenarios and to minimize total economic losses associated with drought-induced irrigation shortages.

Materials and Methods

Study area

The model is applied to the Ararat region of Armenia, a major lowland agricultural area where irrigation is essential due to limited summer precipitation and high evapotranspiration rates (Food and Agriculture Organization, 2016). Crop production in the region depends on multiple irrigation cycles during the growing season. During drought years, available irrigation volumes decline, requiring progressive irrigation restriction measures in order to distribute limited water resources among crops.

Data sources and analytical framework

The prioritization framework is constructed at the crop level using regional agricultural statistics, irrigation schedules and average market prices of agricultural products. The analysis was based on representative regional agricultural, irrigation and economic data for the period 2020–2024. Crop water use, irrigation schedules and yield response assumptions were derived from regional irrigation practices and literature sources relevant to current agricultural conditions in the Ararat region of Armenia.

The analysis is conducted on a per-hectare basis to ensure comparability across different crops and production systems. This approach allows the estimation of irrigation water use, yield changes and economic outcomes under different irrigation scenarios.

Irrigation scenarios

For each crop, three irrigation regimes are defined to represent increasing levels of water scarcity:

Optimal irrigation – full irrigation according to the standard regional irrigation schedule.

Limited irrigation – reduced number of irrigation cycles representing deficit irrigation conditions.

No irrigation – complete withdrawal of irrigation supply.

Seasonal irrigation water use is calculated as:

$$W = n \times V \quad (1)$$

where

n – number of irrigation cycles,

V – water volume per cycle ($m^3\ ha^{-1}$).

The limited irrigation regime reflects a deficit irrigation approach, where water supply is intentionally reduced below full crop evapotranspiration (ETc) while maintaining partial crop productivity (Food and Agriculture Organization, 2002; Fereres & Soriano, 2007).

Yield and economic losses

Crop yield under limited irrigation is estimated using regional production data and agronomic relationships between water deficit and yield reduction. The estimation follows the FAO yield–water production framework, which links relative yield reduction to relative evapotranspiration deficit (Doorenbos & Kassam, 1979; Fereres & Soriano, 2007).

Economic loss resulting from irrigation restriction is calculated as:

$$EL = (Yo - Yr) \times P \quad (2)$$

where

EL – economic loss (EUR ha^{-1}),

Yo – crop yield under optimal irrigation (quintal ha^{-1}),

Yr – crop yield under reduced irrigation (quintal ha^{-1}),

P – crop market price (EUR per quintal).

Water savings

Water savings resulting from irrigation restriction are calculated as:

$$WS = Wo - Wr \quad (3)$$

where

WS – irrigation water saved (m³ ha⁻¹),
Wo – water use under optimal irrigation (m³ ha⁻¹),
Wr – water use under reduced irrigation (m³ ha⁻¹).

Irrigation prioritization index

To rank crops under drought conditions, an irrigation prioritization index is defined as:

$$PI = EL/WS \quad (4)$$

where

PI – prioritization index (EUR m⁻³),
EL– economic loss resulting from irrigation restriction (EUR ha⁻¹),
WS – irrigation water saved (m³ ha⁻¹).

The index represents economic loss per cubic metre of water not applied. Crops with lower index values generate smaller economic losses per unit of water saved and are therefore assigned lower irrigation priority. Crops with higher index values are prioritised for irrigation water allocation during drought conditions.

Progressive restriction logic

The model allows implementation of staged drought response strategies:

Phase 1 – moderate drought

Transition from optimal to limited irrigation, starting with crops that have the lowest prioritization index.

Phase 2 – severe drought

Complete irrigation withdrawal is applied progressively to crops with the lowest economic return per unit of water.

The framework is implemented as a spreadsheet-based decision-support tool that allows recalculation of crop prioritization under different drought severities, irrigation reductions and agricultural price scenarios. This structure enables rapid evaluation of alternative water allocation strategies and supports practical drought management decisions at regional level.

Results and Discussion

Irrigation water use under restriction scenarios

Application of the proposed prioritization framework to irrigated crops in the Ararat region illustrates how irrigation water demand changes under progressive restriction scenarios. Based on the irrigation schedules described in the methodological framework, seasonal water use varies substantially between optimal, limited and no-irrigation regimes.

Under optimal irrigation conditions, crops receive the full number of irrigation cycles required to maintain maximum productivity. When irrigation is partially restricted, the number of irrigation cycles decreases, leading to a corresponding reduction in seasonal water use. Under severe drought conditions, irrigation can be fully withdrawn, resulting in the maximum possible water savings.

Across the analysed crops, moderate irrigation restriction reduces seasonal irrigation water use by approximately 28–45%, depending on crop irrigation requirements and production characteristics. This reduction represents the first stage of drought management, where irrigation is reduced but crop production is partially maintained through deficit irrigation practices.

The irrigation regimes and associated seasonal water use used in the analysis are summarized in Table 1.

Table 1

Irrigation regimes and water use (Ararat example)

Irrigation regime	Irrigation cycles	Seasonal water use (m³ ha⁻¹)	Water saved (m³ ha⁻¹)
Optimal	7	5600	-
Limited	5	4000	1600
No Irrigation	0	0	5600

Economic losses and prioritization index

Under optimal irrigation conditions, the analysed crop produced an average yield of approximately 100 quintals ha⁻¹. When irrigation was reduced, yield declined to about 50 quintals ha⁻¹, while complete withdrawal of irrigation resulted in total crop failure.

Using an average market price of 46.5 EUR per quintal, the estimated economic losses differed substantially between irrigation restriction levels. The transition from optimal to limited irrigation resulted in moderate economic losses associated with partial yield reduction, whereas complete irrigation withdrawal generated significantly higher production losses due to total yield elimination.

These results illustrate the economic trade-off between water savings and agricultural production losses. Moderate irrigation restriction reduces water consumption while maintaining part of the crop yield, whereas complete irrigation withdrawal maximizes water savings but leads to substantially higher economic losses.

The calculated economic losses, associated water savings and resulting prioritization index values are presented in Table 2.

Table 2

Economic losses and irrigation prioritization index under restriction scenarios

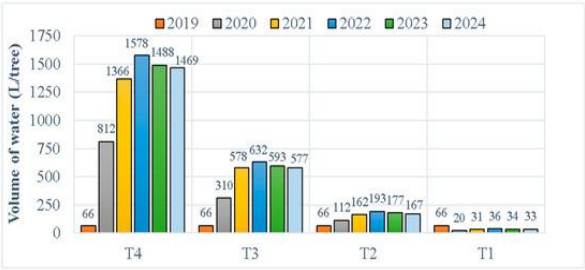
Restriction scenario	Economic loss (EUR ha⁻¹)	Water saved (m³ ha⁻¹)	Index (EUR m⁻³)
Optimal → Limited	2 326	1 600	1.45
Optimal → No irrigation	4651	5600	0.83

Interpretation of the prioritization index

The prioritization index expresses the economic loss associated with each cubic metre of irrigation water not applied. Higher index values, therefore, indicate greater marginal economic productivity of irrigation water and, consequently, higher priority for irrigation allocation during water scarcity.

The results demonstrate that irrigation water has substantially higher marginal economic value under moderate irrigation restriction than under complete irrigation withdrawal. Under limited irrigation conditions, each cubic metre of water not applied results in an economic loss of approximately 1.45 EUR m^{-3}, reflecting the relatively high productivity of irrigation water when crop production is partially maintained.

In contrast, under complete irrigation withdrawal the average economic loss per cubic metre decreases to approximately 0.83 EUR m^{-3}. This occurs because total yield loss is distributed across a larger volume of water savings, reducing the average economic value per unit of water.



This occurs because total yield loss is distributed across a larger volume of water savings, reducing the average economic value per unit of water.

This implies that irrigation water allocation decisions based solely on total water savings may lead to economically inefficient outcomes if differences in marginal productivity are not considered.

These results illustrate the economic rationale for staged irrigation restriction strategies, where partial irrigation reductions are implemented before complete irrigation withdrawal. The comparison of prioritization index values across restriction scenarios is illustrated in Figure 1.

Figure 1

Prioritization index comparison

Crop prioritization under drought conditions

While the prioritization index quantifies the economic value of irrigation water under different restriction scenarios, its practical application lies in ranking crops according to their marginal economic productivity of water. Crops generating higher economic return per cubic metre of irrigation water should receive higher priority during water allocation under drought conditions.

Application of the proposed index to representative irrigated crops in the Ararat region illustrates clear differences in irrigation priority among crop types. The presented irrigation scenarios and economic calculations reflect representative conditions for the 2020–2024 agricultural seasons.

Crops with higher market value and higher sensitivity to irrigation shortages tend to generate greater economic loss per unit of water saved, which results in higher prioritization index values.

Conversely, crops with lower economic return per unit of irrigation water show lower prioritization index values and may be considered for earlier irrigation reduction during drought events. This ranking approach allows irrigation managers to implement staged restriction strategies while minimizing total economic losses in agricultural production systems.

Importantly, the results indicate that crop prioritization should be dynamic and responsive to both economic conditions and water availability, rather than based on fixed allocation rules.

The resulting crop prioritization based on the economic-loss-per-unit-water principle is illustrated in Figure 2.

Figure 2

Crop prioritization ranking based on economic loss per unit of irrigation water

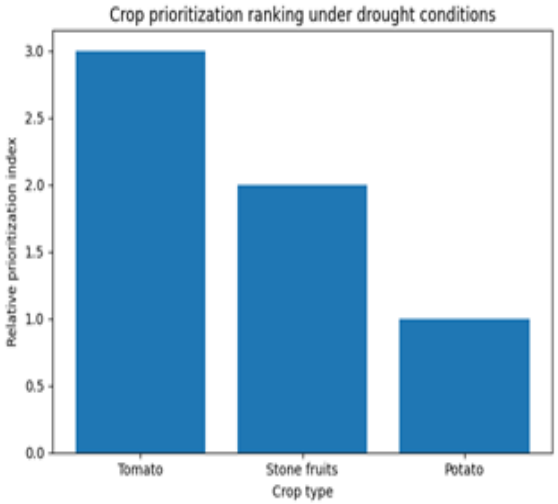


Figure 2 presents the crop prioritization ranking derived from the proposed economic-loss-per-unit-water approach. The results indicate clear differences in the marginal economic productivity of irrigation water among the analysed crops.

Tomato shows the highest prioritization index, reflecting its relatively high economic return per unit of irrigation water. Stone fruits occupy an intermediate position, while potato demonstrates the lowest prioritization index due to its lower economic productivity per cubic metre of irrigation water.

This ranking provides a practical basis for staged irrigation restriction during drought conditions. Crops with lower prioritization index values can be subjected to irrigation reductions earlier, while crops with higher economic value of irrigation water should be maintained under irrigation for as long as possible.

The results demonstrate that irrigation allocation based on economic loss per unit of water can provide a transparent and operational basis for drought

management in irrigated agricultural systems. The prioritization index developed in this study quantifies the marginal economic productivity of irrigation water and allows crops to be ranked according to the economic consequences of irrigation reduction.

The findings indicate that moderate irrigation restriction can significantly reduce water consumption while preserving a substantial share of crop production. This result is consistent with previous research on deficit irrigation, which shows that controlled reductions in irrigation water can maintain acceptable yield levels depending on crop sensitivity and timing of water stress (Fereres & Soriano, 2007; Steduto et al., 2012). In such situations, partial irrigation reductions represent an efficient first response to water scarcity, allowing water savings without immediate full production losses.

The results also highlight that the economic value of irrigation water differs considerably between crops. Crops generating higher economic return per unit of irrigation water require greater protection during drought periods, while crops with lower marginal economic productivity may be subjected to earlier irrigation reductions. Similar economic allocation principles have been widely discussed in water resource economics, where water scarcity requires prioritizing uses that generate the highest economic benefits (Young, 2005; Ward & Michelsen, 2002).

The proposed prioritization framework therefore provides a practical tool for implementing staged irrigation restriction strategies during drought events. By integrating irrigation volumes, crop yield response and market valuation, the model translates water scarcity into operational crop ranking decisions. Such tools are particularly relevant in regions like the Ararat Valley, where irrigation-dependent agriculture faces increasing pressure from climate variability and growing water demand.

Nevertheless, several limitations should be acknowledged. The model relies on representative yield values, average market prices and simplified irrigation regimes, which may vary across farms and seasons. In addition, the framework does not explicitly account for crop growth stage sensitivity, long-term soil effects or social and food security considerations that may influence water allocation decisions. In addition to the presented results, the findings can be interpreted within a broader context of recent advances in water resource management under climate change. Increasing evidence suggests that water scarcity is not only a function of physical water availability but also of allocation efficiency and governance structures. Global assessments indicate that climate change is expected to intensify water scarcity in many agricultural regions, increasing the need for adaptive and economically efficient allocation mechanisms (Schewe et al., 2014).

From an economic perspective, recent studies emphasize that efficient water allocation requires moving beyond uniform distribution practices toward mechanisms that reflect the marginal value of water across competing uses (Grafton et al., 2018). The results of this study support this view by demonstrating that the economic productivity of irrigation water varies substantially between crops and across irrigation regimes.

Furthermore, research on agricultural water productivity highlights that significant improvements in water-use efficiency can be achieved through targeted allocation strategies and deficit irrigation practices, particularly in water-limited environments (Zwart & Bastiaanssen, 2004). The prioritization index proposed in this study provides a practical tool for implementing such strategies by linking agronomic yield response with economic valuation.

While the framework is simplified, it contributes to bridging the gap between theoretical economic principles and operational irrigation management by providing a transparent and easily applicable decision-support approach. This is particularly relevant in data-limited regions, where complex modelling approaches may not be feasible but where efficient water allocation remains critical for sustaining agricultural productivity.

Future research could therefore integrate more detailed agronomic modelling and regional economic data to improve the robustness of irrigation prioritization tools.

Conclusions

1. The case study of the Ararat region demonstrates the applicability of an economic-loss-based prioritization framework for irrigation management under drought conditions.
2. The results show that moderate irrigation restriction can reduce seasonal irrigation water use by approximately 28–45%, depending on crop irrigation requirements. Under such conditions, partial irrigation reductions allow substantial water savings while maintaining a significant share of crop yield.
3. Complete irrigation withdrawal provides the largest potential water savings but results in significantly higher economic losses due to total production failure. The calculated prioritization index shows that the economic loss per cubic metre of water saved varies considerably between irrigation restriction levels and crop types.
4. The proposed prioritization index therefore provides a transparent indicator of the marginal economic productivity of irrigation water and enables ranking of crops according to their economic sensitivity to irrigation reduction. This approach supports staged drought response strategies, where irrigation reductions are first applied to crops generating lower economic return per unit of water.
5. Overall, the developed framework represents a simple and operational decision-support tool that can assist irrigation managers and regional planners in allocating limited water resources during drought events while minimizing total economic losses in

irrigated agricultural systems. The results should be interpreted as indicative rather than statistically generalizable, as the model is based on representative values and simplified assumptions.

A COMPARATIVE ASSESSMENT OF FARM-LEVEL GREENHOUSE GAS EMISSION ESTIMATES USING DECARBFARM AND ESTABLISHED GHG TOOLS

***Katrina Muizniece[1], Inga Grinfelde[1,2], Jovita Pilecka-Ulcugaceva[1]**

Abstract
The foundation of effective agriculture decarbonisation at farm level is the establishment of a comprehensive understanding of the farm's current greenhouse gas (GHG) emission baseline. The establishment of effective baselines and the monitoring of GHG emissions over time are ensured through the provision of farm-level GHG emission calculators available for farmers. As of the present moment there are number of GHG emission calculation tools available for farmers. In addition to these, a new decarbonisation decision support tool (DST), DecarbFarm, is currently under the development. Although the developed DecarbFarm tool is not yet widely available for famers, it is crucial to evaluate DSTs comparability with other, already available GHG DSTs. This research paper aims to evaluate the comparability of GHG emission estimates generated by the DecarbFarm DST by three already established agriculture GHG emission calculators – the Estonian Carbon Footprint assessment tool, the Latvian GHG and Ammonia Emission Calculation tool, and Cool Farm Tool – using harmonised input data. The findings of the study suggest general consistency in total GHG emission estimates across tools, alongside notable variability in source-specific emissions. These differences highlight the influence of methodological choices on estimated emission baselines and have direct implications for farm-level decarbonisation planning. Furthermore, the results underline the importance of region-specific GHG emission calculation tool in more accurately reflecting local emission factors within farm-level GHG baselines.
Keywords: farm GHG emissions, agricultural decarbonization, decision support tools, regional emission factor.

Introduction

Latest Latvian national greenhouse gas (GHG) inventory report indicates, that Latvia's GHG emissions, including land use, land use change, and forestry emissions, have been increasing throughout years 2000 and 2023 (Skrebele et al., 2025). Similar observations can be made regarding the sector of agriculture, however the GHG emission increase in agriculture is more gradual (Skrebele et al., 2025). Within Latvia's national energy and climate action plan for the sector of agriculture the target is set to achieve GHG emission amount of 2,176.33 kt CO_2 eq. in 2030, contributing to the target of reducing 17% of GHG emissions stemming from sectors not included in European Union Emission Trading System (ETS) (Latvijas Republikas Ekonomikas Ministrija, 2024). The plan also acknowledges the difficulties achieving the set target, however it also emphasises the role of non-ETS sector including agriculture's role in achieving Latvia's decarbonisation targets (Latvijas Republikas Ekonomikas Ministrija, 2024).

The foundation of effective agriculture decarbonisation begins at the farm level, specifically with the understanding of farm's GHG emission baseline. This understanding can be established by utilising an effective GHG emission accounting tool suitable for application at farm level. Throughout past couple of decades, several GHG emission accounting tools have been developed, ranging in geographies, methodologies, utilised calculation solutions, focus of the calculator (Colomb et al., 2012; Dzalbs et al., 2023; Jabbour et al., 2021). In Denef et al. (2012) report the earliest developed tool has been identified as developed in 2002. Since then, several more GHG emission accounting tools for agriculture have been developed, allowing farm-level GHG emission accounting to become more accessible all over the world. In case the calculator is easy to use and it's use is not time consuming, the calculator can act also as a tool for awareness raising as an equal goal (Peter et al., 2017).

In the Baltic countries over the past ten years agriculture GHG emission accounting tools have gained increasing attention, driving the development of new tools. Currently there are GHG emission accounting tools available developed by scientific institutions, such as GHG and ammonium emission calculator developed by scientists of Latvia University of Life Sciences and Technology (Grinfelde et al., 2018b), as well as tools developed by the request of governments, such as Carbon Footprint Assessment Tool (CFAT) (Ministry of Regional Affairs and Agriculture of Estonia & Sustinere OÜ, 2024). There is also a GHG emission accounting tool developed by Deloitte after the request of the Baltic banking associations (Deloitte, 2024), however the scope of agriculture production-related accounting options within the tool are significantly smaller than within the other Baltic tools mentioned. The presence of various accounting tools raises the question of whether there are differences among them, and if so, whether those differences in the resulting GHG emission estimates are significant.

In scientific literature there are studies available comparing the available GHG emission accounting tools (Dzalbs et al., 2023; Keller et al., 2014; Sykes et al., 2017), including region-specific agriculture GHG emission accounting tool evaluations (Whittaker et al., 2013). However, the analysis of the Baltic tools is limited. This raises questions, if the tools developed specifically for the Baltic region are comparable with those agriculture GHG emission accounting tools recognised worldwide. Furthermore, given the authors of the study have developed a new GHG emission

accounting tool for farm-level decarbonisation decision-making support in Latvia (Muižniece, 2025), it is important to evaluate how the results generated by this tool compare with those produced by other established agricultural GHG emission accounting tools both locally and internationally.

To find the answers to the abovementioned questions, this research is aimed to evaluate the comparability of GHG emission estimates generated by the DecarbFarm DST by three already established agriculture GHG emission calculators – the Estonian Carbon Footprint Assessment Tool, the Latvian GHG and Ammonia Emission Calculation tool, and Cool Farm Tool – using harmonised input data.

Materials and Methods

The study evaluates four different GHG emission accounting tools for the agriculture (see Table 1). Besides the DecarbFarm tool developed by the authors of this study, the tools for the study were selected primarily focusing on the Baltic region. Based on this criteria, GHG and Ammonium Emission Calculator (Grinfelde et al., 2018b) developed in Latvia and CFAT (Ministry of Regional Affairs and Agriculture of Estonia & Sustinere OÜ, 2024) developed in Estonia were selected. To provide an internationally recognized benchmark within the analysis, a Cool Farm Tool (Cool Farm Alliance, 2026) was selected, due to its applicability to Europe, including the Baltics.

Table 1

Comparison between the tools used in this study

Tool name	Country	Language	Technical solution	Tool focus	Number of input data points	Reference
DecarbFarm	Latvia	Latvian	Excel	Integrated livestock-crop farms	99	(Muižniece, 2025)
Carbon Footprint Assessment Tool	Estonia	Estonian	Excel	Crop farming	1385	(Ministry of Regional Affairs and Agriculture of Estonia & Sustinere OÜ, 2024)
				Livestock	1907	
				Buildings and administration	191	
GHG and Ammonium Emission Calculator	Latvia	Latvian	Web-based	Integrated livestock-crop farms	111	(Grinfelde et al., 2018b)
CoolFarm	United Kingdom	English, Latvian	Web-based	Crop farming	66	(Cool Farm Alliance, 2026)
				Livestock	70	

The tools were screened as of 23rd of February 2026 until 1st of March 2026. For each tool input data points were manually counted, considering, that one data point is one entry field for information, including fields where information from dropdowns is selected. Selections within a dropdown are not counted separately. As within CFAT (Ministry of Regional Affairs and Agriculture of Estonia & Sustinere OÜ, 2024) it was possible to change the tools structure, for the purpose of this study the structure of the tool was not adjusted. For the Cool Farm Tool it is possible to add additional sources of GHG emissions about whom GHG emissions could be provided (Cool Farm Alliance, 2026). In these instances, the input data points were counted only for the first entry. Units, that are directly linked with the input numbers, are not counted as separate input data points.

Given the different parameter scopes of each parameter, five common parameters across the four tools were chosen for which data is collected. The chosen parameters are:

- Dairy cows;
- Swine;
- Wheat;
- Pasture/grassland;
- Natural gas.

For each parameter a randomised input data string consisting of ten data points was developed. These data strings (see Table 2) were after used as inputs in each of the four GHG emission accounting tools. These input data strings were developed to approximate realistic farm ranges. For each input data point the respective output of calculated GHG emission was recorded.

During the data collection process, it was observed that the Cool Farm Tool differed in the chosen parameter's calculation approach, for example, calculating the GHG emissions from wheat as residue management only. In addition, this tool did not provide the option to evaluate the GHG emissions from pasture/grasslands. To maintain the comparability between the tools, the Cool Farm Tool was further excluded from the assessment. In addition, parameter Natural gas was excluded from the assessment due to visibly higher obtained output values from GHG and Ammonium Emission Calculator (see Figure 1).

All data obtained from the tools and included in this study were evaluated to ensure compliance with the assumptions required for parametric statistical analyses. Normality of data distribution was assessed prior to selecting the appropriate statistical test. In case data is normally distributed, a parametric data can be used. Otherwise, the nonparametric Friedman test was used.

Normality was examined using the Shapiro–Wilk test in statistics software RStudio (version 2026.01.0+392) with α = 95% confidence interval. If the recorder p-value is above 0.05, the null hypothesis of normal distribution of data cannot be rejected.

Table 2
Input data used in the tool screening process

Number of input data point	Dairy cows, number of animals	Swine, number of animals	Wheat, t	Pasture/Grassland, ha	Natural Gas, m^3
1	80	500	200	10	1,000
2	102	634	248	12	1,259
3	118	729	292	17	1,695
4	136	851	383	18	1,906
5	142	1,034	437	20	1,993
6	156	1,382	481	21	2,041
7	169	1,544	524	24	2,428
8	172	1,634	561	27	2,682
9	189	1,853	601	29	2,847
10	205	2,000	650	30	3,000

To evaluate differences among GHG accounting tools within each agricultural parameter, the nonparametric Friedman rank-sum test was applied. This test was selected as the dataset represents a repeated-measures design in which identical input levels were evaluated using multiple tools. In this study, the agricultural parameter was considered the block, and the GHG accounting tools were treated as related groups. The test evaluates whether the median rankings of GHG emission estimates differ significantly among tools while controlling for variability attributable to input magnitude.

The Friedman test was performed in RStudio (version 2026.01.0+392) using a significance threshold corresponding to a 95% confidence level. When statistically significant differences were detected at this level, post hoc pairwise comparisons were performed using Wilcoxon signed-rank tests, with Bonferroni-adjusted p-values applied to control the family-wise error rate at α = 0.05. Kendall's coefficient of concordance (W) was used to quantify the magnitude of differences among tools. Kendall's coefficient value provides a standardized measure of agreement among ranks across parameters, with values ranging from 0 indicating no effect to 1, indicating perfect agreement. This test allows interpretation of the practical relevance of the observed differences independently of statistical significance.

The findings of the analysis facilitate the identification of key differences among GHG accounting tools and provide a solid foundation for subsequent research.

Results and Discussion

The Figure 1 presents the registered tool output GHG emissions per parameter. Based on the recorded data it can be seen that obtained GHG emissions from Natural Gas in GHG and Ammonia calculator (Grinfelde et al., 2018b) is visibly higher than other registered GHG emissions both for the same parameter as well as other parameters among the tools, indicating a potential inconsistency for Natural Gas GHG emission calculation. Therefore, Natural Gas as a parameter was excluded from further statistical analysis in order to avoid potential bias resulting from methodological differences in emission calculation approaches among the tools (see Figure 2).

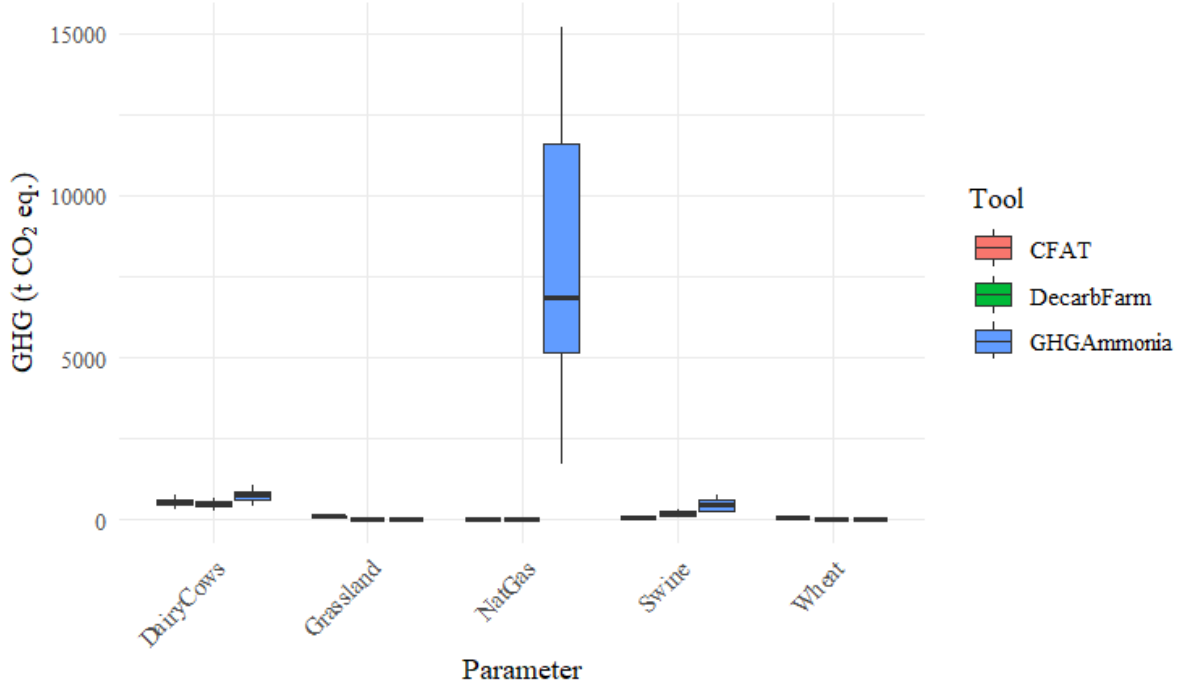
The Shapiro-Wilk normality test revealed the data used in the study are not normally distributed (p = 6.808e - 12). Therefore, nonparametric Friedman test was used to assess the GHG emission estimates provided by the utilised GHG assessment tools.

Comparing the parameter registered output GHG emissions form three different tools, the Friedman test suggest that there are no statistically significant differences (p = 0.082) between the analysed tools. When analysing the GHG emissions between tool pairs applying Wilcoxon signed rank pairwise tests, the results indicate that between DecarbFarm and CFAT there are no differences (p = 1.000), while GHG and Ammonium Emission Calculator was statistically significantly different from both DecarbFarm (p = 0.019) and CFAT (p = 0.021). From a practical perspective, the observed similarity between DecarbFarm and CFAT suggests that the newly developed tool can provide comparable GHG emission estimates for farm-level baseline assessments. These differences in the tools are mainly related with the underlying IPCC methodology version used in the methodology of the tool, as both DecarbFarm and CFAT applies 2019 revision of the guidelines , while the GHG and Ammonium Emission Calculator was mainly based on the 2006 revision of the IPCC guidelines (Grinfelde et al., 2018a).

In addition, Friedman Kendall's W value was calculated. The value of 0.0625 indicate that the differences between tools are statistically small, and the tools produce very similar GHG profiles relative to one another. This indicates weak agreement in rank ordering of GHG values across tools, suggesting that differences between tools are minimal in practical terms. Given that the tools rely on different region-specific GHG emission factors, such minimal

differences, particularly regarding DecarbFarm and CFAT tools, are likely driven more by variations in the underlying emission factor assumptions than by any substantive methodological divergence. Given that assessed tools are developed in the Baltic region, the emission factor impact does not yield significant differences.

Figure 1
GHG emission results obtained from different tools per parameter. The abbreviations used in the figure are as follows: CFAT – Carbon Footprint Assessment Tool, GHGAmmonia – GHG and Ammonium Emission Calculator, NatGas – Natural Gas



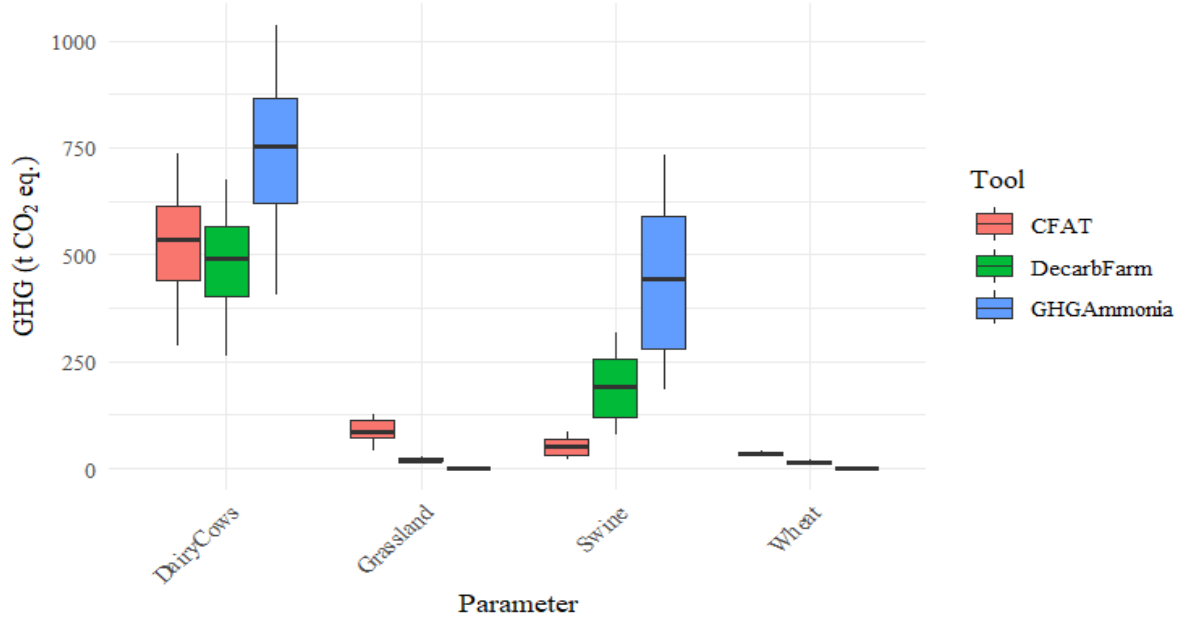


Figure 2
GHG emission results per parameter per tool used in analysis. The abbreviations used in the figure are as follows: CFAT – Carbon Footprint Assessment Tool, GHGAmmonia – GHG and Ammonium Emission Calculator

Whittaker et al. (2013) study evaluated carbon accounting tools for the application in the United Kingdom, analysing also each parameter emissions among the tools, evaluating the differences stemming

from emission factors used in parameter GHG emission estimations. In further research, the data obtained within this study can be further evaluated also considering the statistical differences between the chosen parameters separately.

While the results of the analysed tools indicate that these tools statistically are not significantly different and can be used by farmers in the Baltic region without notable restrictions against the use of tool. Besides the underlying methodology and regional aspects of the tool, Dzalbs et al. (2023) in their study evaluated other aspects crucial for farmers for successful adaptation in everyday aspects. Those cover several characteristics, such as usability, assessment simplicity, and recognition among peers (Dzalbs et al., 2023). The authors suggest in further research to assess these aspects of the tools used within this study.

Additionally, the applicability of these analysed calculators could depend on the level of details required to be provided for GHG emission estimations. Peter et al. (2017) study evaluated GHG emission calculators for the energy crop production. They concluded that the analysed tools either provided ease of use leading to reporting driven results, or required more detailed and time-consuming data inputs, therefore allowing farmers to gain insights on more granular calculated output level (Peter et al., 2017). All four tools initially included in this study exhibit potential for application not only for reporting purposes, but also for more detailed analysis of key GHG emission sources. However, due to the limitation of one-year GHG emission calculation, more detailed and continuous analysis would be difficult.

Given the limitations in obtaining comparable data for the Cool Farm Tool, the comparability of Baltic GHG emission accounting tools with other internationally recognised tools remains limited. Therefore, the authors suggest further evaluation of established GHG emission accounting tools by expanding the range of tools included in the analysis, which would enable a statistical comparison of Baltic tools with a broader set of internationally used calculators.

Conclusions

1. The tools assessed generate comparable GHG emission results, with differences stemming from underlying methodology and region-specific emission factors.
2. The analysed tool practical use may vary depending on usability, data requirements, and the level of detail required for GHG emission assessment.
3. To understand the effects of regional emission factors, the selected tools should be statistically compared on a parameter level.
4. Further analysis can be conducted to evaluate factors influencing the practical adoption of these tools in real-world factors.
5. Future research should include a broader range of GHG emission accounting tools to enable statistical comparison between the Baltic and internationally recognised calculators.

Abstract
Persistent synthetic chemicals known as per- and polyfluoroalkyl substances (PFAS) are widely detected in aquatic environments and are recognized as contaminants of concern in surface waters worldwide. Although agricultural areas are not typically considered primary PFAS sources, rural catchments may act as transport pathways where hydrological processes and surface runoff influence PFAS mobility and distribution. This study presents a comparative assessment of PFAS occurrence in river basins in Latvia: the Daugava River Basin, representing a mixed urban–rural catchment, and the Lielupe River Basin, characterised by intensive agricultural land use. The analysis focuses on perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA), two indicator PFAS compounds included in national monitoring programs. Monitoring data from multiple stations were evaluated for the period 2017–2025 in the Daugava River Basin and 2018–2024 in the Lielupe River Basin using descriptive statistics and non-parametric statistical analysis. No statistically significant differences in PFOS and PFOA concentrations were observed between the Daugava and Lielupe river basins (Kruskal–Wallis test, $p > 0.05$). In contrast, concentrations differed significantly between PFOS and PFOA ($p < 0.001$) and among individual monitoring stations, suggesting the influence of local contamination sources and localised spatial differences. These findings indicate that PFAS occurrence in rural surface waters is influenced by local environmental conditions and catchment characteristics. The study highlights the importance of river basin monitoring for understanding PFAS distribution and supports the need for more systematic PFAS monitoring in agricultural regions of the Baltic area.
Keywords: PFAS, PFOS, PFOA, surface water, river basins.

Introduction

Per- and polyfluoroalkyl substances (PFAS) represent a large group of synthetic chemicals widely used in industrial processes and consumer products due to their unique physicochemical properties, including high thermal stability and surfactant behaviour. According to Buck et al. (2011), PFAS comprise a diverse class of fluorinated compounds characterised by strong carbon–fluorine bonds, which contribute to their exceptional environmental persistence (Buck et al., 2011). Because of their resistance to degradation and extensive historical use, PFAS are now recognised as globally distributed contaminants detected in various environmental compartments, including surface waters, groundwater, sediments, and biota (Brusseau, 2023; Gomis et al., 2015; Ackerman Grunfeld et al., 2024; Alam et al., 2024). Numerous monitoring studies have demonstrated their widespread occurrence in aquatic environments across different regions of the world, indicating that PFAS contamination has become a global environmental concern (Ahrens, 2010; McMahon et al., 2022; Calore et al., 2023; Miladinova et al., 2024).

Among the numerous PFAS compounds, perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA) are among the most widely studied substances due to their persistence, mobility, and environmental relevance. These compounds are frequently detected in rivers and other surface water bodies worldwide, where they may originate from multiple anthropogenic sources such as industrial discharges, wastewater treatment plant effluents, landfill leachates, and diffuse emissions from urban and rural areas (Sun & Li, 2025; Tang et al., 2023). Urban environments and wastewater systems have been identified as important contributors to PFAS contamination in aquatic ecosystems, as demonstrated by Yang et al. (2025).

Rivers play an important role in the environmental transport and redistribution of PFAS, acting as pathways that connect terrestrial emission sources with downstream aquatic ecosystems and marine environments (Cai et al., 2018; Byrne et al., 2024). The occurrence and distribution of PFAS in river basins are influenced by various environmental processes, including hydrological transport, catchment characteristics, and interactions with environmental matrices such as dissolved organic matter and suspended particles. Previous studies have shown that organic carbon and particulate matter can influence the mobility and distribution of PFAS in aquatic systems (Li et al., 2022).

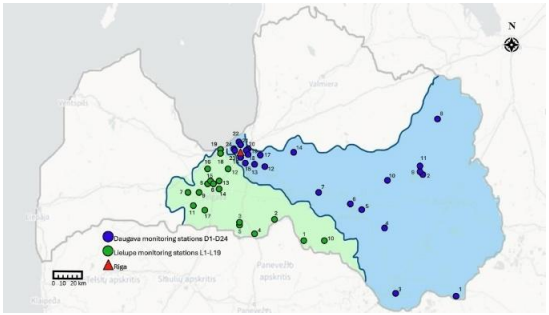
Although PFAS contamination is often associated with industrialised or highly urbanised regions, rural catchments may also act as important pathways for PFAS transport. Diffuse pollution processes, surface runoff, and soil–water interactions may contribute to the mobilisation of PFAS in agricultural landscapes. In addition, the application of sewage sludge and biosolids to agricultural soils has been recognised as a potential secondary source of PFAS in the environment (Zhou et al., 2024).

Studies conducted in Nordic and Baltic regions have increasingly reported the presence of PFAS in surface waters, indicating that these contaminants are also widespread in northern European aquatic environments. For example, Kärrman et al. (2019) and Soerensen et al. (2024) reported detectable PFAS concentrations in Nordic and Baltic surface waters, highlighting the importance of regional monitoring and improved understanding of PFAS transport processes in these catchments (Kärrman et al., 2019;

Soerensen et al., 2024).

In addition to growing scientific attention, PFAS contamination has also become an important regulatory concern. Within the European Union, several PFAS compounds are subject to environmental monitoring and regulatory control due to their persistence and potential risks to ecosystems and human health (European Parliament and Council, 2008; EC, 2022). However, PFAS monitoring data in Latvian river basins remain limited, and studies addressing spatial and temporal variability of PFAS in surface waters are still scarce.

The present study provides a comparative assessment of PFOS and PFOA occurrence in two major Latvian river basins with contrasting land-use characteristics: the Daugava River Basin, representing a mixed urban–rural system, and the Lielupe River Basin, which is strongly influenced by agricultural activities. Despite the existence of national environmental monitoring data, studies interpreting PFAS distribution patterns and variability in Latvian river systems remain limited. Using national monitoring data, this study evaluates the spatial and temporal variability of PFOS and PFOA occurrence in surface waters and examines potential differences in PFAS distribution between river basins and individual monitoring stations. Spatial variability between monitoring stations may reflect differences in land use, urban influence, wastewater inputs, and hydrological conditions within river catchments. Therefore, analysing PFAS occurrence at both river basin and monitoring station level is important for understanding local contamination patterns and potential PFAS sources under Latvian conditions. This study provides new evidence on the spatial and temporal distribution of PFOS and PFOA in Latvian surface waters at the river-basin scale.



Materials and Methods

This study focuses on two major river basins in Latvia: the Daugava River Basin and the Lielupe River Basin, which represent catchments with contrasting land-use characteristics. The Daugava River Basin is characterised by a mixed urban–rural landscape including major urban areas and diverse land-use patterns, whereas the Lielupe River Basin is strongly influenced by agricultural activities and intensive land use. Catchment characteristics and land-use patterns were interpreted descriptively based on the general characteristics of the river basins reported in previous studies and regional environmental information.

PFAS occurrence was assessed using available surface water monitoring data obtained from the Latvian Environment, Geology and Meteorology Centre (LVĢMC) (LVĢMC, 2026). Monitoring stations included in this study represent official surface water monitoring sites located within the Daugava and Lielupe river basins. The spatial distribution of monitoring stations included in the analysis is presented in Figure 1. A total of 43 surface water monitoring stations included in the study were located throughout the Daugava (24) and Lielupe (19) river basins. Stations in the Daugava River Basin included: *Daugava (further – DA) Piedruja-Latvijas-Baltkrievijas-robeža (D1), Rēzeknes grīva (D2), DA 1.5 km lejpus Daugavpils (D3), Dubnas 2.5 km augšpus Līvāniem (D4), DA 1.0km-augšpus Jēkabpils (D5), DA 1.5km lejpus Jēkabpils (Zeļķu tilts) (D6), Pļaviņu ūdenskrātuve 1.0km augšpus Aizkraukles (D7), Balvu ezers vidusdaļa (D8), Lubāna ezers vidusdaļa (D9), Kujas grīva (D10), Aiviekste augšpus Ičas (D11), DA augšpus Ogres (D12), Rīgas ūdenskrātuve 1.0 km lejpus Lipšiem (D13), Mergupes grīva (D14), Ķekavas grīva (D15), DA pie Rumbulas (D16), Lielā Jugla 0.2 km augšpus Zaķiem hidroprofils (D17), Juglas ezers vidusdaļa (D18), Lielais Baltezers vidusdaļa (D19), Mazais Baltezers pie sūkņu stacijas (D20), Ķīšezers pretī Mežaparkam (D21), Mārupītes grīva (D23), Ķīšezers pretī Mīlgrāvja caurtekai (D22) and DA Andrejosta (D24). Stations in the Lielupe River Basin included: Mēmele Latvijas–Lietuvas robeža Rises (L1), Mēmele 0.5 km lejpus Skaistkalnes (L2), Mēmeles grīva (L3), Mūsa Latvijas–Lietuvas robeža (L4), Mūsas grīva (L5), Iecavas grīva (L6), Bērze 1.0 km lejpus Dobeles (L7), Bērzes grīva (L8), Auce lejpus Nākotnes (L9), Saukas ezers vidusdaļa (L10), Tērvete augšpus Tērvetes ciema (L11), Misa 1.5 km lejpus Olaines (L12), Misas grīva (L13), Lielupe 1.0 km augšpus Jelgavas (L14), Lielupe 2.5 km lejpus Jelgavas (L15), Lielupe 0.5 km lejpus Kalnciema (L16), Vilces grīva (L17), Babītes ezers vidusdaļa (L18) and Lielupe Majori (L19).*

Figure 1

Map of monitoring stations in the Daugava and Lielupe river basins

The analysis focused on two widely monitored indicator compounds: perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA). PFOS and PFOA concentrations from the Daugava River Basin were analysed for the period 2017–2025, while data from the Lielupe River Basin covered the period 2018–2024. The monitoring data represent episodic sampling events conducted within the national surface water monitoring programme.

Water samples collected within this period in each basin were tested in accredited laboratories using liquid chromatography coupled with tandem mass spectrometry (LC–MS/MS), which is a widely used

analytical technique for PFAS determination in environmental samples. PFOS and PFOA concentrations were originally reported in micrograms in the available monitoring datasets. However, in this study, results were converted to nanograms per litre (ng L^{-1}) in order to compare with other studies and regulatory norms.

In total, 892 surface water samples were analysed for both PFOS and PFOA, including 504 samples from the Daugava River Basin and 388 samples from the Lielupe River Basin.

To evaluate the occurrence of both compounds in the two river basins, descriptive statistical analysis was performed. The calculated statistical parameters included minimum, maximum, mean, median, standard deviation, skewness and kurtosis (Table 1).

Spatial variability of PFAS concentrations between the two river basins was explored using graphical visualization techniques. Differences in PFOS and PFOA concentrations between the Daugava and Lielupe river basins were illustrated using boxplot diagrams, which allow comparison of data distribution, median values, and potential outliers between datasets (Figure 3).

Temporal variability of PFOS and PFOA concentrations was analyzed by evaluating annual patterns of PFOS and PFOA concentrations over the monitoring period. Temporal trends were illustrated using annual concentration plots showing changes in PFOS and PFOA levels during the study period (Figure 5).

Because environmental monitoring data showed non-normal distribution, differences between groups were evaluated using non-parametric statistical tests. The Kruskal–Wallis test was applied to assess differences between river basins, compounds, monitoring stations, and years. When statistically significant differences were detected, Dunn's post-hoc test with Bonferroni correction was used to identify pairwise differences between groups.

All data processing, graphical visualisation, and statistical analyses were performed using R statistical software.

Table 1

Descriptive statistics of PFOS and PFOA concentrations (ng L^{-1}) in the Daugava and Lielupe river basins during the monitoring period

Basin	Compound	n	mean	median	sd	min	max	skewness	kurtosis
Daugava	PFOA	252	0.5605	0.203	1.3290	0.039	13.221	7.15	61.32
Daugava	PFOS	252	0.1282	0.052	0.7162	0.039	11.106	14.48	216.71
Lielupe	PFOA	194	0.5366	0.194	0.9754	0.039	9.202	4.69	32.48
Lielupe	PFOS	194	0.0829	0.040	0.1494	0.039	1.928	10.01	117.65

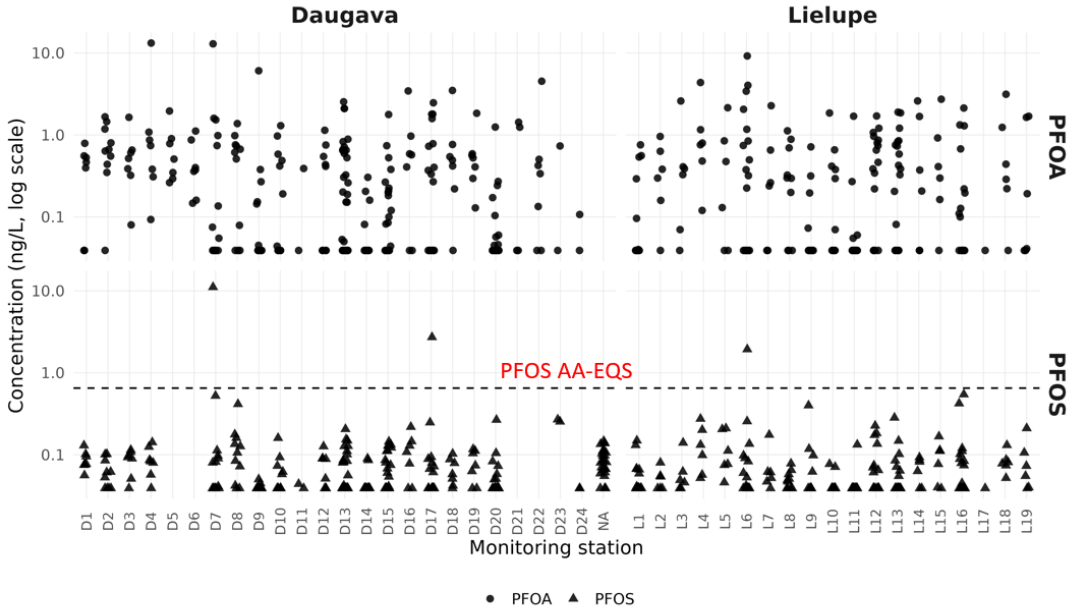
Results and Discussion

The results are presented in three main analytical steps. First, the overall concentration levels and detection frequencies of PFOS and PFOA in the studied river basins are summarized. Second, differences between the Daugava and Lielupe river basins are analysed. Finally, temporal variability of PFOS and PFOA concentrations during the study period is examined.

Spatial variability of PFOS and PFOA

The occurrence of PFOS and PFOA in the two river basins was evaluated in order to identify spatial differences associated with catchment characteristics and land-use patterns. Descriptive statistical analysis of the monitoring dataset is presented in Table 1. Overall, PFOS and PFOA concentrations were relatively low in both river basins and exhibited comparable concentration ranges. In most samples, PFOS concentrations remained below the PFOS AA-EQS threshold (0.65 ng L^{-1}), while PFOA concentrations were also observed within relatively low concentration ranges, suggesting relatively low background contamination levels in the Daugava and Lielupe river systems.

Across the monitoring period, PFOS concentrations were typically observed within the range of approximately 0.04–0.1 ng L^{-1}, whereas PFOA concentrations were generally higher, most frequently ranging between 0.1 and 0.5 ng L^{-1}. This pattern is consistent with observations from other European monitoring studies, where PFOA is often detected at slightly higher concentrations due to its higher environmental mobility and lower sorption affinity compared with PFOS (Tang et al., 2023; Cai et al., 2018).



Descriptive statistical analysis indicates that overall concentration patterns in the two river basins are relatively similar. Median concentrations of both compounds differed only slightly between the Daugava and Lielupe river basins. This observation is supported by the results of the Kruskal–Wallis statistical test, which did not reveal statistically significant differences between PFAS concentrations in the two river basins ($p > 0.05$). The descriptive statistical parameters presented in Table 1 also provide additional insight into the distribution characteristics of PFOS and PFOA concentrations in the studied river basins. The calculated skewness values indicate a strongly right-skewed distribution for both compounds, particularly for PFOS in the Daugava River Basin. This suggests that most observations are

concentrated at relatively low concentrations, while a limited number of measurements represent substantially higher values.

Similarly, the high kurtosis values observed in several datasets indicate the presence of extreme observations compared with a normal distribution. Such statistical patterns are typical for environmental contaminant datasets, where concentrations often exhibit strong variability due to episodic inputs or localised emission sources. In the present study, the observed skewness and kurtosis values confirm that PFAS concentrations are dominated by background levels with occasional elevated measurements, which appear as outliers in the graphical analysis. These statistical characteristics further support the use of non-parametric methods such as the Kruskal–Wallis test for analysing differences between groups. In contrast, statistically significant differences were observed between the two analyzed compoundsWhen PFOS and PFOA concentrations were compared across all monitoring data, the Kruskal–Wallis test indicated a significant difference between the compounds ($p < 0.001$), confirming that PFOA concentrations were generally higher than PFOS concentrations in both river basins. The distribution of PFOS and PFOA concentrations across individual monitoring stations is illustrated in Figure 2, where each point represents a single monitoring observation.

Figure 2

Distribution of PFOS and PFOA concentrations across monitoring stations in the Daugava and Lielupe river basins. The dashed line indicates the PFOS AA-EQS value (0.65 ng L⁻¹)

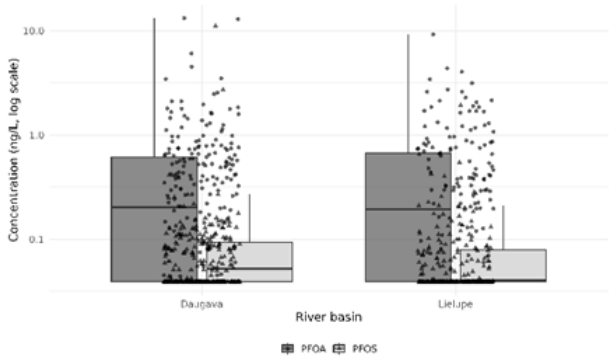
The graphical representation shows that the majority of measurements cluster within a relatively narrow concentration range corresponding to background levels, while several monitoring stations exhibit elevated values that may indicate localised contamination sources. Additionally, the dashed line in the PFOS panel indicates the Annual Average Environmental Quality Standard for PFOS in surface waters (AA–EQS = 0.65 ng L^{-1}). The results show that the majority of PFOS measurements were well below this regulatory threshold.

Although statistically significant spatial differences among monitoring stations were detected within both river basins (Kruskal–Wallis test, $p < 0.001$), the post-hoc Dunn test with Bonferroni correction showed that only a limited number of station pairs differed significantly. Some monitoring stations exhibited more distinct concentration patterns compared with other sites, particularly D20 in the Daugava River Basin and L4 in the Lielupe River Basin. Nevertheless, the limited number of statistically significant pairwise differences suggests that PFOS and PFOA occurrence was influenced mainly by localised conditions or episodic inputs rather than consistent basin-wide spatial gradients.

The spatial variability observed between monitoring stations may reflect differences in land use, population density, and wastewater management within the river catchments. In the Daugava River Basin, several monitoring stations with elevated concentration variability are located in areas influenced by urban development, particularly in the vicinity of the Riga metropolitan region. Urban areas are frequently associated with PFAS emissions originating from wastewater treatment plants, stormwater runoff, and industrial activities.

In contrast, the Lielupe River Basin is characterised by extensive agricultural land use. Although agricultural areas are not typically considered primary sources of PFAS contamination, diffuse pollution processes may

contribute to the transport of these substances through surface runoff and soil–water interactions. In addition, the application of sewage sludge or biosolids to agricultural soils has been identified as a potential pathway for PFAS introduction into rural environments.



These contrasting catchment characteristics may partly explain the localised concentration differences observed between monitoring stations, indicating that both urban and agricultural processes may contribute to PFAS transport within river systems. A notable feature of the dataset is the presence of several elevated concentration values compared with the overall concentration range. These higher values appear as outliers in the graphical analysis and may reflect episodic PFAS inputs or localised contamination sources, such as wastewater discharges, stormwater runoff, industrial releases, or other temporary emission events.

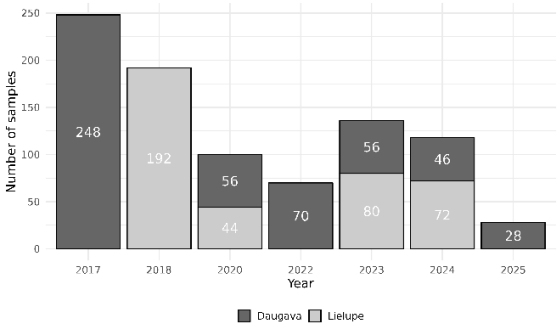
Rivers are known to act as effective transport pathways for PFAS, redistributing contaminants from terrestrial environments to aquatic systems (Brusseau, 2023). The comparative distribution of PFOS and PFOA concentrations between the two river basins is further illustrated in Figure 3, which presents boxplot diagrams showing median values, interquartile ranges, and outliers. The results demonstrate that most PFOS concentrations were substantially lower than PFOA concentrations in both river basins.

The observed spatial variability and episodic elevated concentrations demonstrate the complexity of PFAS occurrence in surface waters and underline the need for continued monitoring at both river basin and local scales.

Figure 3

Comparison of PFOS and PFOA concentration distributions between the Daugava and Lielupe river basins

A large proportion of PFOS concentrations were observed close to approximately 0.039–0.04 ng L^{-1}. This clustering likely reflects the analytical quantification limit (LOQ) of the applied laboratory method rather than a uniform environmental background concentration. Similar patterns have been reported in other PFAS monitoring datasets where concentrations frequently approach analytical detection limits due to the trace-level occurrence of PFAS in surface waters.



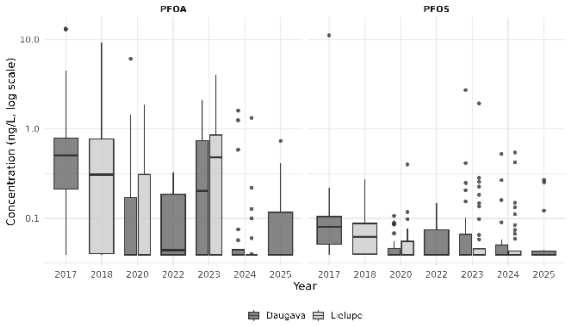
Temporal variability of PFAS occurrence

Temporal patterns of PFAS monitoring were evaluated by analyzing annual distributions of PFOS and PFOA concentrations across the study period. The number of collected samples varied substantially between years and river basins, reflecting the episodic nature of monitoring (Figure 4).

The sampling frequency was highest in 2017 in the Daugava River Basin and 2018 in the Lielupe River Basin, particularly, while fewer observations were recorded in several later years. Differences in monitoring intensity between years should therefore be considered when interpreting temporal patterns.

Figure 4

Number of PFOS and PFOA samples collected per year in the Daugava and Lielupe river basins during the monitoring period



Annual concentration patterns of PFOS and PFOA are illustrated in Figure 5, which presents boxplots of concentration distributions for each year and river basin. Statistical analysis indicated significant temporal variability in PFAS concentrations during the monitoring period ($p < 0.05$). When analyzed separately, both PFOS and PFOA showed significant differences between years ($p < 0.05$), indicating that PFAS occurrence in the studied river basins varies over time. Such temporal variability may be influenced by changes in hydrological conditions, seasonal runoff dynamics, and variability in local emission sources.

Hydrological processes can play a significant role in the temporal dynamics of PFAS concentrations in surface waters. Variations in precipitation, river discharge, and seasonal runoff may influence the mobilization and transport of contaminants within river catchments. During periods of increased runoff, contaminants accumulated in soils or sediments may be transported into river systems, resulting in temporarily elevated concentrations.

In addition to hydrological variability, differences in monitoring intensity between years may also influence the observed temporal patterns. As shown in Figure 4, the number of collected samples varied considerably throughout the monitoring period, with higher sampling frequency during certain years. Such variations in monitoring coverage may affect the interpretation of long-term trends and highlight the importance of consistent and systematic monitoring

programmes for evaluating PFAS dynamics in aquatic environments.

Figure 5
Annual variability of PFOS and PFOA concentrations during the monitoring period

Overall, the spatial and temporal patterns observed in this study are consistent with previously reported patterns of PFAS distribution in European river systems, where contamination is typically characterized by relatively low background concentrations combined with occasional elevated values linked to local emission sources (Li et al., 2023; Byrne et al., 2024; Soerensen et al., 2024).

These findings suggest that PFOS and PFOA occurrence in the studied Latvian river basins is largely influenced by diffuse pollution sources and regional contamination patterns rather than by a single dominant point source.

The results of this study contribute to the growing body of research on PFOS and PFOA occurrence in European river systems and provide new insights into distribution of both compounds in Latvian surface waters. Although PFOS and PFOA contamination is often associated with highly industrialized regions, the present findings demonstrate that both urban–rural and agricultural catchments may act as pathways for transport of both compounds in the environment.

In urbanized catchments, PFOS and PFOA contamination is frequently linked to wastewater treatment plant effluents, stormwater drainage systems, and industrial discharges. Rivers located downstream of large cities may therefore receive continuous inputs of PFAS compounds originating from various anthropogenic activities. The Daugava River Basin, which includes the largest urban area in Latvia, represents an example of such mixed urban–rural catchment conditions.

At the same time, agricultural catchments may also contribute to PFAS compound transport through diffuse pollution processes. Agricultural landscapes may receive those chemicals through atmospheric deposition, irrigation water, or the application of sludge-based fertilizers. Once present in soils, these compounds may be mobilized through surface runoff and transported into nearby rivers and streams.

Similar patterns have been reported in other Nordic and Baltic studies, where contamination of PFAS compounds is typically characterized by relatively low background concentrations combined with occasional elevated values associated with local emission sources (Kärrman et al., 2019; Soerensen et al., 2024). Comparable PFAS pollutants occurrence patterns have been documented in regional monitoring studies across Nordic and Baltic surface waters, highlighting the widespread distribution of these compounds in northern European aquatic environments (Filipovic et al., 2013; Junttila et al., 2019).

The findings of the present study are therefore consistent with broader regional observations and highlight the importance of continued PFAS compound monitoring in river basins across the Baltic region.

Conclusions

1. The study evaluated the occurrence of two indicator PFAS compounds, PFOS and PFOA, in surface waters of two major Latvian river basins with contrasting land-use characteristics. The results confirm that PFOA and PFOS are detectable in both the Daugava and Lielupe river basins, indicating the presence of these persistent contaminants in surface waters across the studied catchments.
2. Comparative statistical analysis revealed no statistically significant differences in PFOA and PFOS concentrations in the two river basins ($p > 0.05$), suggesting that overall PFOA and PFOS contamination levels are broadly comparable in the Daugava and Lielupe river systems.
3. In contrast, statistically significant differences were observed between the two analyzed compounds ($p < 0.001$). PFOA concentrations were generally higher than PFOS concentrations in both river basins, reflecting differences in environmental mobility and behavior of these compounds.
4. Significant spatial differences between monitoring stations were detected within both river basins ($p < 0.001$). However, post-hoc analysis indicated that only a limited number of station pairs differed significantly, suggesting that PFOS and PFOA occurrence was influenced mainly by localised conditions or episodic inputs rather than consistent basin-wide spatial gradients.
5. Temporal analysis demonstrated significant differences between monitoring years ($p < 0.001$), indicating that PFOS and PFOA concentrations in surface waters vary over time and may be influenced by hydrological conditions, episodic pollution events, or changes in emission patterns.
6. These results suggest that continued monitoring may help improve understanding of PFAS occurrence and temporal variability in Latvian surface waters. Improved long-term monitoring and integrated assessment approaches may further contribute to understanding the distribution and behaviour of PFAS compounds in river catchments of the Baltic region.

Abstract
Water resource governance in Latvia, particularly for surface waters as rivers and lakes, are facing local stakeholder participation and voluntary initiatives growth in some municipalities, but, in general, remains institutionally fragmented with limited governance capacities and insufficient cross-sectoral coordination, especially, within local river basins, being subject of this study - approaching water resource governance as necessarily and complementary multi-sectoral, multi-stakeholder and multi-instrumental (triple governance dimensions frame) governance processes within two characteristic surface-water case territories to identify preconditions for strengthening capacities and qualities of water resources management. The research applied a case study research methodology complementary including document analysis, field observations, local-regional stakeholder mapping, and in-depth semi-structured interviews with all governance stakeholder groups. Findings indicate that water resource governance in the country remains statutory not yet complete, vertically and horizontally fragmented; stakeholder involvement is not overall spread and often realised as formal consultation processes. Cross-sectoral integration between water resource management and related agriculture, fisheries, recreation and tourism, etc. local development sectors, remains not sufficiently developed. Meantime, local river basin case studies demonstrate that societal NGO-based bottom-up governance initiatives can to some extent compensate or even substitute limited national and local governmental capacities and instrumentation - NGOs can function as important co-management institutions for natural resources, providing communication and facilitating various stakeholders' engagement, multi-instrumental consultation and communication programs and processes, carrying out practical resources management activities. Administrative recognition and support for local inhabitants-based NGOs and community-based co-management practices are to be elaborated and integrated into water resources governance system.
Keywords: water governance, cross-sectoral, stakeholders, participation, bottom-up governance approaches.

Introduction

Since its adoption in 2000, the European Union's Water Framework Directive (WFD) (2000/60/EC) has fundamentally transformed water resource management across Europe by promoting an ecosystem-based and sustainability-oriented approach to water governance. The directive introduced river basin districts as the primary planning and management units, replacing fragmented administrative approaches with integrated governance based on hydrological boundaries (Hering et al., 2010). A central principle of the WFD is the active involvement of stakeholders and the public in water management processes, recognising that effective governance requires coordination across multiple sectors, administrative levels, and societal actors. Despite these policy advances, stakeholder participation and governance effectiveness remain uneven across Europe, particularly in smaller river basins and peripheral regions with limited institutional capacity (Neto et al., 2017).

Contemporary water challenges are increasingly viewed not merely as issues of physical water scarcity or environmental degradation but as governance challenges arising from fragmented decision-making, institutional complexity, and insufficient coordination among responsible actors (OECD, 2011). As a result, growing attention has been given to governance approaches that emphasise shared responsibility between governmental institutions, civil society, private stakeholders, and resource users. These approaches seek to improve policy coherence, strengthen institutional adaptability, and increase societal engagement in decision-making processes (Julio et al., 2021).

Effective water governance is widely recognised as a multi-level and multi-actor process involving both formal institutional arrangements and informal practices. Within this context, Integrated River Basin Management (IRBM) has emerged as a key framework promoting the holistic management of water resources, land use, and ecosystems across hydrological boundaries rather than administrative jurisdictions (Jaspers, 2003). The effectiveness of IRBM depends on the ability of governance systems to facilitate cooperation across sectors and scales while addressing the complexity of socio-ecological systems (SES), where ecological processes and human activities are closely interconnected (OECD, 2015; Huffy, 2011).

To address these challenges, several governance models have been developed, including co-governance, network and adaptive governance. These approaches emphasise collaboration among public authorities, non-governmental organisations (NGOs), private actors, local communities, and scientific institutions, thereby fostering social learning, institutional resilience, and adaptive capacity (Kooiman & Jentoft, 2009; Turton et al., 2007). Participatory governance approaches are particularly important in complex SES contexts, where multiple interests, knowledge systems, and management objectives intersect. By involving stakeholders directly in decision-making processes, governance systems can improve legitimacy, strengthen local ownership, and

enhance the long-term effectiveness of environmental management measures (Julio et al., 2021).

The Organisation for Economic Co-operation and Development (OECD) has further advanced the understanding of water governance through its Principles on Water Governance, which identify effectiveness, efficiency, and trust and engagement as the three core dimensions of successful governance systems (Akhmouch & Clavreul, 2016). These principles emphasise the importance of clearly defined institutional roles, policy coherence across sectors, stakeholder involvement, transparency, and adaptive management mechanisms. Although widely recognised in policy and academic discourse, their implementation remains uneven, particularly at local and regional levels with limited governance capacity, resources, and coordination (Jiménez et al., 2024).

To better address the complexity of water governance, this study draws upon the Triple governance dimensions framework (Ernsteins et al., 2017, 2025). The framework conceptualises governance through three complementary dimensions: governance content, governance instruments, and governance stakeholders. Governance content (esp. cross-sectorial applicability and water-nature-food nexus) is examined through a socio-ecological systems (SES) perspective, reflecting the interconnected nature of environmental, social, and economic processes. Governance instruments comprise policy, planning, institutional, economic, technological, and communication mechanisms that support governance implementation and development. Governance stakeholders represent various actors involved in governance processes, together with their interests, responsibilities, participation, and interactions. Combined, these dimensions provide a framework for analysing water governance challenges and opportunities across multiple sectors and administrative levels.

The two case study areas selected for this research were chosen not only for their relevance to water resource governance but also for their strong focus on nature conservation, particularly within Natura 2000 territories. This highlights the importance of the water–nature nexus and its broader potential to extend towards water–nature–food interactions through activities such as agriculture and fisheries. Furthermore, both territories demonstrate established examples of society-driven governance practices, including active NGO involvement and well-developed communication mechanisms. These areas have previously been subject to research and are currently being further examined within the Horizon-Widera project BETTER LIFE, which aims to advance transformative and socially engaged research approaches.

Emerging evidence from various river basin initiatives demonstrates the potential of place-based and participatory governance approaches. The Catchment-Based Approach (CaBA) in the United Kingdom illustrates how local stakeholder networks can contribute to improved environmental outcomes, stronger community engagement, and enhanced governance legitimacy (Neto et al., 2017). Similarly, experiences from the Ebro River Basin in Spain and the Tucson Basin in the United States indicate that structured stakeholder participation can strengthen institutional adaptability and governance capacity, although outcomes remain highly dependent on local political, social, and institutional contexts (Ballester & Mott Lacroix, 2016; Megdal et al., 2017).

Despite growing international experience, significant knowledge gaps remain regarding the practical implementation of participatory and delegated governance approaches in smaller river basins and protected nature areas operating within highly centralised governance systems. While substantial research has focused on national and regional water governance, less attention has been paid to how local actors can complement formal governance arrangements in areas with limited institutional capacity and complex water–nature interactions.

This challenge is particularly relevant in Latvia. Water governance under the WFD is largely centralised, with river basin management coordinated at national level. Although national legislation provides opportunities for delegating specific public administration functions to public and private entities when such arrangements improve governance effectiveness (The Parliament of the Republic of Latvia, 2002; The Parliament of the Republic of Latvia, 2022; Guidelines, 2020), practical implementation remains limited. Nevertheless, several examples indicate the potential of more participatory governance models. Governance assessments conducted in Cesis Municipality have highlighted the advantages of delegated management arrangements in improving administrative efficiency and clarifying institutional responsibilities. Similarly, local NGO involvement in the Dviete River basin demonstrates how bottom-up initiatives can contribute to the management of Natura 2000 territories and flood-prone landscapes where state institutional presence is limited. However, such initiatives remain largely project-based and have not yet become systematically integrated into broader water governance frameworks.

The need for more effective governance arrangements is particularly evident in protected river basins and wetland territories where environmental management requires cooperation among multiple sectors and stakeholder groups. In such areas, water management objectives are closely linked to biodiversity conservation, agricultural activities, fisheries, tourism, and local community development, creating complex governance environments that cannot be effectively addressed through sectoral approaches alone. Strengthening participatory, cross-sectoral, and adaptive governance may improve both water resource management and nature conservation outcomes.

Against this background, this study examines the potential of participatory, cross-sectoral, and delegated governance approaches to strengthen water and nature

resource management in Latvia. Using the Dviete River Basin and Lake Lubans Basin as case studies, the research analyses governance structures, stakeholder interactions, and opportunities for bottom-up co-management within Natura 2000 territories. Particular attention is given to the role of local actors, institutional cooperation, and governance capacities that may contribute to more integrated, adaptive, and socially inclusive water governance practices.

Materials and Methods

The study explored all three complementary governance system dimensions simultaneously through a collaborative governance process perspective, examining governance sectors, governance instruments, and governance stakeholders within the selected case territories. This approach responds to the combined demands of both formal nature conservation and water resource governance frameworks.

Subsequently, this study examines multi-sectoral, multi-stakeholder, and multi-instrumental governance processes in two water resource management case areas in Latvia: the Dviete River Basin and the Lake Lubans region as small, subordinated basins in one out of fore River Water Basin Districts. Particular attention is given to participatory and bottom-up governance approaches supporting Natura 2000 management and the implementation of the EU WFD in territories as two cases selected where national and regional governance capacities are limited.

The primary objective was to identify the key preconditions needed to strengthen sustainable water resources governance locally, with a particular focus on advancing participatory and co-management practices, as well as developing effective governance instruments at the local level.

The study is focusing on two small sub-basins as for river catchment and lake region - both case study areas were selected for their progress in water resource governance and their strong focus on nature conservation, particularly within Natura 2000 sites. This highlights the significance of the water-nature nexus and its broader potential. In both regions, this relationship often extends to include water-nature-food linkages, especially through activities such as agriculture and fisheries.

Furthermore, both areas demonstrate established, society-driven local management practices, including active involvement of NGOs and well-developed communication mechanisms. These territories have already been subject to research in EU Horizon and LIFE Nature projects, respectively, and are now being further examined by our partner universities.

Daugava River Basin District

As required by the EU WFD, each river basin district has its own management plan (RBDMP) for a six-year planning cycle. In Latvia, four river basin districts have been established: Daugava, Gauja, Lielupe, and Venta. The first RBDMP in the European Union was elaborated for the Daugava River Basin District during 2000–2003. In this study, the Daugava River Basin District was characterised as the upper governance and management level for the two selected river sub-basins.

The Daugava River Basin is one of Latvia's most significant hydrological and ecological regions, spanning diverse biogeographical zones, including lowland river valleys, boreo-nemoral forests, and floodplain meadows. It supports numerous protected habitats and species and is characterised by a high level of biodiversity. The total length of the Daugava River is 1,005 km, of which 352 km are located within Latvia. The Latvian part of the basin covers 27,057 km², representing 42% of the national territory.

Land cover within the basin consists of approximately 52% forests, 20% agricultural land, 14% wetlands, 3% lakes, and 0.4% urbanised areas. The basin includes both rural and urban territories and supports economic activities such as hydropower generation, agriculture, forestry, and nature tourism. In 2019, the Daugava River Basin District had a population of approximately 1.14 million inhabitants, representing about 59% of Latvia's total population.

Administratively, the basin fully or partially includes 29 administrative units in Latvia, consisting of 23 rural municipalities and 6 state cities, including capital city Riga. The transboundary nature of the river, which flows through EU Eastern border neighbour countries before reaching Latvia, adds an international governance dimension requiring cross-border coordination.

Dviete River Basin

The Dviete River Basin case study was conducted within the EU Horizon project OPTAIN (2021–2026), which focuses on identifying effective strategies for retaining and reusing water and nutrients in small agricultural catchments under different soil and climate conditions across Europe.

In Latvia, the project is implemented within the Dviete River Basin, covering approximately 250 km², including the Dviete floodplain. The Dviete floodplain was designated as a Natura 2000 protected area in 2004 and covers approximately 4,989 hectares. The protected territory was established to preserve natural floodplain meadows, which represent ecologically diverse habitats and important bird gathering and nesting sites.

The area is located within the Upper Daugava and Jekabpils municipalities in southeastern Latvia and is recognised as one of the larger nature parks in the country.

Lake Lubans region

The Lake Lubans Basin case study was examined within the EU LIFE GOODWATER IP project, which focuses on implementing Latvia's River Basin Management Plans to achieve good surface water status.

The study area is located within the Lake Lubans region and forms a central part of the Lubans Wetland, a Natura 2000 site and a protected area of international

importance recognised under the Ramsar Convention. Covering more than 47,900 hectares, it is the largest protected nature territory in Latvia. The wetland complex was established in 2009 through the consolidation of eleven previously separate protected areas into a single management territory.

Lake Lubans itself covers approximately 80 km² and is the largest lake in Latvia as well as the largest dammed lake in Europe. The surrounding wetland has developed from the historical floodplain of the lake and is located primarily within Rezekne and Madona municipalities in central-eastern Latvia.

The research was carried out as a multi-stage, combining several project-based studies during the period from 2022 to 2025 and in both cases, the importance of community participation in water basin management and nature protection governance was emphasised. In the Lubans lake/wetland area, management functions of the municipality-built wetland tourism information centre were for long period delegated to a local NGO, which has for over a decade successfully provided nature/environmental communication via all related instruments of information, education, public engagement, and promotion of pro-environmental behaviour.

Meanwhile, in the Dviete River Valley, a voluntary civil association of the managers of local parishes and nature-culture protection enthusiasts has been active since 2003, taking on state-like functions in managing the Natura 2000 territory on a voluntary and enthusiasm-driven basis. Additionally, the wider Daugava River Basin was analysed as a case of structured public participation supported by the EU WFD, demonstrating multi-level governance in river basin management.

A research and development (R&D) approach was employed within the case studies framework, partly incorporating elements of socially engaged research (SES). This methodology combined document analysis across local cases and different governance levels with stakeholder mapping and in-depth interviews. It also included site-based fieldwork, involving visits, observations, and visual documentation such as photographs and videos.

The initial tasks in both case studies are to conduct stakeholder mapping. This mapping process was based on a five-main-stakeholder-group model approach (stakeholder governance dimension), categorised into five distinct but complementary governance stakeholders' segments: state, municipalities, businesses, mediators (including media, educators, NGOs, and academia), and society.

In both case studies, interviews were conducted representing also the majority of relevant policy sectors. These included representatives of national-level government institutions, covering water, nature, environment, and agriculture in both cases and additionally fisheries, forestry, tourism, and culture sectors in the Lake Lubans case, thus reflecting a broad range of SES sectors as well as their regional branches.

The Lake Lubans case included around 60 supplementary short interviews, primarily with members of statutory established inhabitants Consultative Councils as of any local administrative community. In-depth interviews were conducted with representatives from the five main complementary stakeholder groups recognised across all three levels of governance and administration, including those from key policy sectors currently involved or expected to be involved, as well as experts. In total, nearly 40 in-depth semi-structured interviews were conducted in the Lake Lubans region case, along with express interviews mentioned. Similarly, almost 30 in-depth semi-structured interviews were conducted in the Dviete River Basin case, including 5 interviews conducted with regional and national stakeholders relevant also to the broader Daugava River Basin management case.

Results and Discussion

As part of this study, we will specifically examine the Daugava River Basin, one of the four WFD-designated basins in Latvia, which includes both the Lubans sub-basin and the Dviete sub-basin. The Dviete and Lubans water basin regions were selected as case studies due to their comprehensive governance assessment processes. However, within the scope of this paper, the focus is placed specifically on challenges related to cross-sectoral policy development and on innovative societal practices in local governance.

1. Daugava river basin district: status, planning and participatory management

The governing bodies of river basin districts in Latvia and their functions are defined by the Water Management Law. The Latvian Environment, Geology and Meteorology Centre (LEGMC), under the Ministry of Climate and Energy (restructured in 2023), prepares and updates river basin management plans and programmes of measures. The State Environmental Service monitors implementation and, based on LEGMC water quality analyses, reviews conditions of water use permits in line with regulations.

LEGMC maintains the River Basin Management Information System (RBIS), which provides publicly accessible data on surface and groundwater bodies, including their location, quality status, pressures, and planned measures. The system enables users to visualise water quality over time and access detailed environmental datasets. The LEGMC website also offers free downloads of data on meteorology, hydrology, air quality, groundwater, and surface water, supported by public funding.

The governing structure involves several ministries, primarily the Ministry of Climate and Energy, alongside the Ministry of Health (drinking and bathing water) and the Ministry of Agriculture (melioration, fishing), with indirect involvement from ministries responsible for economy, business, and transport.

This multi-ministerial involvement reflects the socio-ecological nature of water management but also leads

to a fragmented governance system. Although IRBM is formally centralised, in practice it is weakly coordinated and limits stakeholder participation. Financial resources remain insufficient for planning, monitoring, implementation, and infrastructure, with many activities, such as river restoration, monitoring improvements, and nature protection, relying on project-based funding rather than stable budgets.

Under the EU Water Framework Directive, four River Basin District Advisory Councils (RBDACs) have been established to support planning. These councils aim to coordinate interests among public authorities, municipalities, NGOs, businesses, and other stakeholders in achieving environmental objectives, operating under Cabinet Regulation No. 681 (2003).

Each council consists of up to 18 members, including representatives from key ministries, planning regions, and NGOs representing environmental protection, water users, and landowners. NGO representatives are nominated every six years through LEGMC-organised processes.

In the Daugava basin, the inter-municipal NGO 'Daugava Union' represents local governments along the river and contributes expertise on water management, protection, and sustainable development. It actively participates in council meetings, promotes inter-institutional cooperation, and represents municipal interests. Other NGOs include the Small Hydropower Association, Environmental Protection Club, Farmers' Parliament, and the Baltic Environmental Forum.

Since 1995, the 'Daugava Union' has addressed a wide range of regional issues, including environmental protection, cultural heritage preservation, pollution reduction, fish resource restoration, and regional identity strengthening, alongside social and economic development goals.

Although council protocols are publicly available, meetings occur only 1–2 times per year and are often formal. Due to bureaucratic and funding constraints, discussions on water quality and measures are limited. As a result, councils have weak influence, creating a gap between their objectives and local needs, and many stakeholders feel underrepresented.

Latvia's third River Basin Management Plan shows some ecological improvement, with waters in good or high status increasing from 21% to 32.5%. However, major challenges remain: no surface waters achieve good chemical status due to pollutants such as mercury and PAHs, and risks persist for groundwater. Monitoring coverage is limited, data inconsistencies remain, and implementation of pollution-reduction measures is insufficient.

The European Commission's 7th implementation report confirms these challenges, highlighting EU-wide gaps in achieving water quality goals. Latvia, like many Member States, is unlikely to meet 2027 targets without stronger action.

Key EU recommendations for Latvia include improving monitoring, addressing pressures, enhancing implementation, increasing transparency, and strengthening coordination. Weak administrative capacity and the absence of clearly assigned management responsibilities remain major issues, along with limited collaboration with municipalities.

Similar capacity constraints exist in communication and participation. Despite EU recommendations to improve transparency, stakeholder engagement, and implementation of WFD Article 14, current approaches remain fragmented and non-systemic, reducing the effectiveness of governance instruments.

2. Towards cross-sectorial policies in sub-basins: participation

Comparing two comparatively diverse water basins, which are also contextually quite close, there are to be recognised a quite a number of similarities and perspectives for water and nature further governance, local bottom-up or co-management deeds, already complementing or even substituting (Dviete case) capacities lacking governmental institutions.

Dviete River basin catchment area and Natura 2000 site

In the Dviete River basin, traditional measures aimed at accelerating water and nutrient runoff in rural areas, such as drainage and land melioration, are increasingly being reconsidered. At the EU level, there is growing support, including financial instruments, for small-scale and nature-based solutions that help reduce or delay runoff. Experiences from such initiatives, including the H2020 OPTAIN project, highlight the importance of collecting, evaluating, and sharing practical knowledge.

The findings reveal important insights regarding policy effectiveness and coherence. Many respondents deemed existing sectoral policies misaligned and poorly suited to current challenges. Particularly low compatibility was noted in relation to water scarcity, water quantity management in agricultural fields, and nutrient recovery from water bodies. Broader issues of fragmented and incoherent legislation were also emphasised. Stakeholders across governance levels, especially at the national level, highlighted persistent disconnects between sectors such as agriculture, nature protection, and water management, often reflecting differing objectives and weak coordination.

Perceptions among sectors varied: representatives of the nature sector generally argued that biodiversity concerns are not adequately integrated into broader policies, while actors from other sectors sometimes perceived the opposite. Additionally, inconsistencies in data and monitoring systems across sectors further complicate integrated decision-making, making it difficult for stakeholders to align their efforts and achieve common goals.

Implementation challenges were widely identified, including administrative and cross-sectoral barriers, difficulties in translating policy into practice, and limited institutional capacity. Communication issues, such as low awareness, weak information exchange, and unclear terminology, were also major obstacles to

effective governance.

To address these challenges, stakeholders proposed several improvements. These include strengthening coordination and policy coherence across sectors (nature, environment, agriculture, and economic activities such as tourism), spatially aligning sectoral priorities, clarifying stakeholder roles and responsibilities, and enhancing mutual understanding between governance domains. Greater emphasis was also placed on improving information sharing, stakeholder engagement, and education, both formal and informal, as well as expanding the use of digital communication tools.

Lake Lubana region area and Natura 2000 site

In contrast, governance in the Lake Lubans basin is heavily dominated by a formal nature protection framework. This is primarily overseen by the regional agency of the national Nature Conservation agency, alongside hydrotechnical regulations managed by the Ministry of Agriculture - both of which face challenges stemming from contradictory priorities. This dual structure creates tensions and limits development in sectors such as fisheries, agriculture, forestry, tourism, and cultural activities, particularly due to the absence since 2009 of a long-term integrated nature protection plan (approved only in 2025) for the Lubana Wetland Natura 2000 area.

Governance in the Lubans region has exhibited fragmentation and insufficient inclusivity from a socio-ecological systems (SES) perspective. Stakeholders from socio-economic sectors have historically been under-represented, with limited involvement beyond the tourism sector. Local residents and entrepreneurs also lacked adequate information and opportunities for participation, which has further exacerbated the fragmentation of governance and limited the effectiveness of collaborative efforts in the region.

Overall, the management of the Lake Lubans area remains weakly coordinated. Institutions tend to operate within their respective sectors with limited collaboration, hindering a shared vision for sustainable regional development. Yet, such a vision is crucial for addressing the diverse challenges faced by the Lake Lubans area and ensuring effective resource management. Stakeholders widely recognise the need for improved communication and cooperation, emphasising the importance of initiating a joint, multi-stakeholder governance planning process. Such an approach should aim to establish a more collaborative governance system that addresses the entire lake region as an integrated territory, rather than focusing solely on the wetland.

3. Towards societal practices in sub-basins: communication and management

This subsection examines community-driven bottom-up initiatives that partly compensate for insufficient governmental and municipal institutional capacity in nature and water resource governance and communication. It focuses in detail on two such initiative centres: the Dviete River Valley management and communication centre and the Lake Lubans communication and management centre, which operate as multifunctional, participation-based instruments for strengthening nature conservation and water governance.

Dviete River Valley management and communication centre

The NGO ʻAssociation of Dviete Valley Municipalities was established in 2004 as a coalition of local municipal staff and committed local enthusiasts, with a specific focus on the protection of natural and cultural heritage in the Dviete River Valley. Over time, the NGO has evolved into the key locally rooted actor in coordinating nature governance, community engagement and knowledge transfer in this rural sub-basin.

The Dviete floodplain Nature Park, designated in 2009, is located in the Dviete river basin in the Selonia region on the left bank of the Daugava River and has been recognised as an important habitat for plant and bird species. The main settlements in the Dviete basin are small rural villages and small towns, including Bebrene (331 inhabitants), Dviete (220 inhabitants) and Kaldabruņa (52 inhabitants), which form the social and institutional context for the NGO's activities. The nature park covers about 4 989 ha, which corresponds to approximately 19% of the Dviete River basin, and is designated as a Natura 2000 site.

In practice, the NGO is the only organisation that undertakes the day-to-day management of the Natura 2000 area, acting on a voluntary and project-based basis without regular financial or technical support from the Nature Conservation Agency or municipality. The association effectively manages almost the entire territory of the nature park, carrying out a wide range of practical conservation tasks. These include maintaining semi-natural grasslands to prevent succession and overgrowth; repairing and maintaining fences; organising and supervising nature-based grazing with semi-wild herbivores; and ensuring the provision of winter fodder. In addition, the NGO actively applies for and implements externally funded projects to secure resources for park management and infrastructure maintenance.

In 2008, the association established the ʻGulbji' Information Centre in a culturally and historically significant building within the Dviete River valley. The centre was created with the explicit aim of providing visitors, local residents, school groups and other interested stakeholders with information about the natural assets and cultural-historical values of the Dviete River Valley. It also serves as a knowledge hub for the management of biologically valuable grasslands and the practical organization of nature-based grazing, offering on-site explanations, demonstrations, and advisory support. All in all, the Dviete NGO could already be recognised as a site-based communication and semi-formal administrative-institutional instrument for local nature protection and water governance.

Lubana Lake tourism, communication and management centre

Over time, the centre, being built and established by the Madona municipality during the execution of the EU LIFE project in 2004, has been very successfully run and developed by the youth nature friends local NGO (2009-2022 under the leasing contract) and steadily evolved from a basic tourism and nature information point at the shore of Lubana Lake into a multifunctional and multi-instrumental Wetland Information Centre (WIC).

Today, the WIC performs several interconnected roles – serving not only as a regional hub for environmental communication and tourism information but also delivering education and training activities that promote environmentally responsible behaviour among a wide range of target groups. The centre has increasingly engaged in local and regional planning processes, particularly in the field of nature protection, by collaborating with governmental and non-governmental organisations to influence policy decisions and promote sustainable practices. As a result, it has gradually developed a comprehensive set of communication functions, including information dissemination, education, stakeholder participation, and the promotion of pro-environmental practices.

In addition, WIC fulfils important semi-administrative and institutional functions. It acts as an intermediary between the Nature Protection Agency and all other interest groups – various groups of local residents; diverse groups of visitors; businesses; tourism operators; and governmental agencies and municipalities – while also collaborating with NGOs, educators, and the media. The centre plays a key role in guiding visitors' behaviour by providing information on regulations, permitted activities, and restrictions within protected areas of NATURA 2000, covering a great part of the River/Lake Basin.

Through coordinated action among key governmental-municipal stakeholders, the WIC has the potential to evolve into a site-based communication and semi-formal administrative-institutional instrument for local nature protection and water governance. Due to limited capacity in governmental and municipal nature and water management institutions, including the Regional Nature Protection Agency responsible for Lubans Lake and the Natura 2000 territory, there is a shortage of local administrative, advisory, and communication staff; currently, only regional inspectors are available.

Table 1 provides a comparative overview of governance instruments and institutional roles in the Dviete and Lake Lubans Natura 2000 sub-basins, highlighting both similarities and key differences in local governance approaches. The Association of Dviete Valley Municipalities demonstrates a strong bottom-up, practice-oriented role, effectively compensating for limited governmental capacity by undertaking day-to-day management and conservation activities. In contrast, the Lubans Wetland Information Centre operates primarily as a communication and intermediary platform, bridging gaps between institutions and stakeholders while supporting education, participation, and policy processes. Across both cases, communication, collaboration, and project-based funding emerge as essential instruments, reflecting the importance of integrated and multi-level governance in addressing the challenges of water and nature management (Table 1).

Table 1

Comparison of Governance Instruments and Institutional Roles in the Dviete River and Lake Lubans Natura 2000 Sub-basins

No.	Governance instruments	Association of Dviete Valley Municipalities	Lubans Wetland Information Centre
1	Regulatory instruments	Implements Natura 2000 requirements in the Dviete floodplain (e.g. grassland management, grazing), partly compensating for limited state capacity	Explains Natura 2000 regulations, rules, and permitted activities to visitors and local residents
2	Planning instruments	Contributes to local-level nature management planning; implements project-based territorial development and conservation activities	Participates in regional planning processes, especially in nature protection; collaborates with institutions to influence policy
3	Economic and financial instruments	Actively attracts external funding (e.g. EU projects) to ensure maintenance of the nature park and infrastructure	Operates through project funding (e.g. LIFE), develops ecotourism, provides services (guided tours, accommodation)
4	Administrative and institutional instruments	Functions as a de facto site manager on a voluntary basis, carrying out day-to-day management of the Natura 2000 area without stable governmental support	Acts as an intermediary between the Nature Protection Agency and stakeholders; performs semi-administrative and advisory functions
5	Infrastructure instruments	Maintains grazing infrastructure, fences, nature trails; ensures winter fodder; manages the 'Gulbji' Information Centre	Develops and maintains the centre, exhibitions, birdwatching sites, and tourism/recreation infrastructure

No.	Governance instruments	Association of Dviete Valley Municipalities	Lubans Wetland Information Centre
6	Communication instruments	Provides knowledge transfer (e.g. on biologically valuable grasslands and grazing), organises educational activities, engages local communities	Strongly developed communication role: guided tours, educational programmes, stakeholder engagement, promotion of environmentally responsible behaviour
7	Collaboration instrument	Cooperates with municipalities, local communities, and international projects (e.g. H2020 OPTAIN); promotes bottom-up governance	Collaborates with municipalities, NGOs, entrepreneurs, researchers, and organisations (e.g. Latvian Ornithological Society), building multi-actor networks

Conclusions

This study explored water resources and nature protection governance in two case territories in Latvia. The findings highlight the importance of cross-sectoral integration, stakeholder participation, and local governance instruments in supporting sustainable governance.

1. This study demonstrates that the main challenge of IRBM in Latvia is not the absence of formal governance structures but their limited effectiveness in practice. Although the Daugava River Basin operates within a well-established WFD governance framework and benefits from extensive environmental data systems, implementation remains constrained by fragmented institutional responsibilities, weak cross-sectoral coordination, limited administrative capacity, and insufficient financial resources. The findings highlight the need for stronger integration of governance sectors, stakeholders, and governance instruments to translate policy objectives into coordinated action and achieve sustainable water management outcomes.

2. The Dviete River Basin case demonstrates how local NGOs can successfully compensate for limited governmental capacity in Natura 2000 management. Our findings show that the Association of Dviete Valley Municipalities as local experienced NGO not only plays a key role in community engagement, and knowledge transfer, but also voluntarily administers and manages the Natura 2000 territory on a day-to-day basis without stable governmental financial support, relying largely on project-based funding and local initiative. This provides a strong example of effective bottom-up management in rural areas.

3. The Lubans Lake case reveals that governance remains fragmented due to weak coordination between sectors and limited stakeholder involvement. The study identifies the municipality-based, locally knowledgable NGO that operates the Wetland Information Centre as a key intermediary; by strengthening communication, participation, and cooperation, the NGO demonstrates potential for developing a more integrated governance model for the region.

4. The study shows that stakeholder participation within Latvian river basin governance remains largely procedural rather than genuinely participatory. Existing mechanisms, including River Basin District Advisory Councils, provide opportunities for consultation but have limited influence on decision-making and implementation processes. The findings highlight the need for more inclusive and continuous engagement of local actors to strengthen governance effectiveness and support integrated water management objectives.

5. The study identifies insufficient cross-sectoral understanding as one of the key barriers to sustainable water resource and nature resource governance. The findings reveal persistent disconnects between conservation-focused sectors (water management and nature conservation) and production or development sectors (agriculture, tourism, fisheries, and local development), particularly within Natura 2000 territories. This highlights the need to move beyond sector-specific governance towards integrated socio-ecological governance approaches**.**

6. The application of the Triple Governance Dimensions Systems Framework proved useful in demonstrating the importance of cross-sectorality, participation, and co-management for effective water and nature resources governance. The findings suggest that governance performance depends on the integration of governance sectors, stakeholders, and governance instruments rather than on formal institutional arrangements alone.

7. The Dviete River Basin and Lake Lubans area case studies demonstrate that bottom-up and participatory governance approaches can partially compensate still limited governmental and municipal capacities - there are growing cases of co-management practice. Local initiatives have contributed to stakeholder cooperation, environmental communication, and the implementation of management activities that would otherwise be difficult to achieve through formal governance structures alone.

8. The Dviete and Lubans examples demonstrate that local governance initiatives can perform multiple functions simultaneously within water and nature resource governance. They compensate for limited governmental capacities, strengthen NGO and community participation, facilitate cooperation between top-down and bottom-up actors, and support practical co-management of Natura 2000 territories. The findings further suggest that such initiatives contribute to building local governance capacity, experience, and confidence among civil society actors, thereby strengthening long-term governance resilience.

9. The study identifies two complementary local governance models that support sustainable water and nature resource management: a non-governmental management approach in Dviete and a tourism-communication management approach in Lubans. Both models demonstrate how governance functions can be delegated to or assumed by, local actors where governmental capacities are limited.

10. Overall, the study demonstrates that sustainable water resources governance is shaped by the interaction of governance sectors, stakeholders, and governance instruments. The findings highlight that cross-sectoral integration, stakeholder participation, and co-management arrangements are essential components of adaptive and resilient water governance, particularly in socio-ecologically complex territories such as Natura 2000 areas.

11. The findings suggest that strengthening participatory governance, improving cross-sectoral cooperation, and enhancing multi-level coordination between national, regional, municipal, and local actors are essential prerequisites for more resilient and adaptive water and nature resources governance in Latvia. Further recognition and integration of local NGOs, information-communication centres, other institutionalised community initiatives within formal governance systems could significantly improve the implementation practice of both water and nature resource management objectives.

Abstract
A comparative case study research (CSR) approach was applied using the Triple Governance Dimensions framework, which examines governance processes through governance sectors, governance stakeholders and also instrument dimensions. Three contrasting environmental and water governance cases were analysed: a comparatively advanced municipality with a pro-environmental administrative profile; a local river basin located largely within a single municipality; and a local lake-region basin representing a multi-municipal lake-wetland system. The CSR complementary combined document analysis, field visits, local-regional stakeholder mapping and in-depth interviews. Statutory municipal environmental management frameworks, including those related to water governance, are formally established but exhibit functional gaps in both multi-level vertical coordination and horizontal cross-departmental governance, together with broader institutional weaknesses caused by weak coordination and limited stakeholder participation. A local-scale river basin management approach remains only weakly developed, even though planning and monitoring documents exist for Latvia's four main river basin districts at the national level. Municipalities do address the water quality and management of individual rivers and lakes, but these activities are usually shaped by limited financial and institutional capacity and are often carried out independently of a river basin approach, partly because of weak national support, limited communication, and insufficient cooperation with the municipal level. Key constraints include limited institutional and financial capacity, insufficient complementarity among governance instruments, weak environmental communication, and fragmented cross-sectoral coordination. Governance effectiveness depends primarily on the degree of integration among governance sectors, instruments, and stakeholders rather than on the mere formal existence of governance arrangements.
Keywords: environmental governance, water governance, governance instruments, stakeholder participation, socio-ecological systems.

Introduction

Environmental governance has become a key framework for addressing complex environmental issues in which ecological, social, institutional, and political factors intersect. Environmental governance refers to the systems, institutions, processes, stakeholders, and instruments that shape environmental decision-making (Lemos & Agrawal, 2006; de Loë et al., 2009). Emerging in response to the limitations of traditional command-and-control approaches, contemporary environmental governance recognises the environment as a complex socio-ecological system (SES) that requires integration, flexibility, collaboration, and the inclusion of diverse knowledge sources (Levin, 1998; Berkes et al., 2003; Folke et al., 2005). Adaptive governance is particularly important in this context, emphasising stakeholder interaction, responsiveness, and the capacity for effective, equitable, and transparent environmental governance (Olsson et al., 2007; Bennett et al., 2018; Nesbit, 2019).

Water governance has emerged as one of the most important fields of environmental governance, reflecting growing recognition that water crises are often governance failures rather than purely resource-related problems (OECD, 2011; Ernsteins et al., 2025). Water governance encompasses the political, social, economic, and administrative systems that shape water use and management, including both formal and informal institutional arrangements (OECD, 2011, 2015). Effective water governance therefore requires not only technical water management but also institutional capacity, stakeholder participation, multi-level cooperation, and cross-sectoral coordination, capable of balancing environmental protection with socio-economic development needs (Konkovs et al., 2022; Julio et al., 2021).

Within the European Union, the Water Framework Directive (WFD), adopted in 2000, established an integrated ecosystem-based approach to water management based on river basin districts as the principal management units (Hering et al., 2010). The Directive introduced a transition from fragmented and pollution-orientated approaches to more comprehensive and sustainability-oriented water governance. It also emphasised the stakeholder involvement in the preparation, implementation, and evaluation of management plans for river basins. However, the implementation of these principles continues to face challenges in many contexts, particularly regarding integrated water resources management, stakeholder participation, communication, and coordination across governance levels and sectors (Rimmert et al., 2020; Neto et al., 2018).

These challenges are particularly relevant in Latvia. Despite more than two decades of river basin governance under the WFD framework, smaller river basins and lake territories continue to experience governance difficulties associated with limited administrative capacity, insufficient planning instruments, fragmented institutional arrangements, and constrained national and local resources (Ernsteins et al., 2017b; Konkovs et al., 2022). Municipal environmental governance remains predominantly sector-based, resulting in only partial implementation of integrated water resources management approaches.

Consequently, improving water governance requires stronger stakeholder involvement, enhanced cross-sectoral cooperation, and governance structures grounded in SES thinking. Additional guidance is provided by the OECD Principles on Water Governance, which emphasise effectiveness, efficiency, and trust and engagement through clearly defined institutional responsibilities, policy coherence, stakeholder participation, transparency, monitoring, and institutional capacity (Akhmouch & Clavreul, 2016; Julio et al., 2021). Nevertheless, available evidence suggests that these principles have not yet been fully implemented in many locally significant water territories in Latvia, particularly in smaller river basins and lake catchments where governance arrangements often remain fragmented and weakly integrated.

Although environmental governance and water governance have both been addressed in Latvian policy and planning practice, there remains a need for comparative analysis of how governance is organised and implemented across different territorial contexts and governance settings. In particular, limited attention have been devoted to the comparison of municipal environmental governance systems with smaller river basin territories that lack formal integration into municipal statutory planning frameworks. Understanding these differences is important for identifying governance strengths and weaknesses, as well as opportunities for more integrated and adaptive management approaches.

To address this gap, the present study applies the Triple Governance Dimensions framework (Ernsteins et al., 2017b), which examines governance through three complementary dimensions: governance content (what), governance stakeholders (who), and governance instruments (how). Using this framework, the study analyses and compares environmental and water governance in three territorial cases in Latvia representing different governance and ecological contexts: Kekava Municipality, Lake Lubans, and the Dviete River Basin.

The first governance dimension concerns governance sectors, which represent the substantive content of environmental governance. Traditionally, governance focused on specific sectors, particularly environmental infrastructure and protected natural areas, but research has demonstrated the limitations of such a narrow approach (Ernsteins et al., 2025). As environmental problems and solutions are embedded within broader SESs, governance must extend beyond isolated sectors and incorporate linkages with health, education, agriculture, forestry, tourism, culture, and other domains (Ernsteins et al., 2017b). Consequently, environmental governance involves not only nature protection and pollution control but also the integration of ecological considerations into cross-sectoral territorial planning and decision-making, supporting broader sustainability goals that connect environmental, social, and economic dimensions.

The second governance dimension focuses on stakeholder groups. Environmental governance recognises that effective governance cannot be achieved by the state alone and therefore requires the participation of public institutions, municipalities, businesses, households, NGOs, educators, the media, scientists, and consultants (Ernsteins et al., 2017b). These actors are grouped into five segments: the state, municipalities, business, society, and mediators. Mediators, including NGOs, the media, educators, and academia, play a particularly important role in communication, knowledge sharing, and collaboration (Ernsteins et al., 2017b). This approach is consistent with frameworks such as the Quintuple Helix, which emphasise cross-sectoral cooperation and the integration of diverse perspectives and expertise (Schütz et al., 2019; Morawska Jancelewicz, 2021). Stakeholder participation throughout the governance cycle, from analysis to evaluation, strengthens knowledge integration, learning, acceptance, and implementation, thereby making it a core component of adaptive environmental governance (Kochskamper et al., 2016; Ernsteins et al., 2017b).

The third governance dimension concerns governance instruments, which translate governance objectives into practice. It distinguishes six complementary groups of instruments (Ernsteins et al., 2017b): infrastructure and technologies, economic and financial instruments, communication instruments, institutional frameworks, planning approaches, and legal regulations. Effective environmental governance requires a balanced combination of legal, financial, organisational, technological, planning, and communication instruments, tailored to specific contexts. Communication instruments are particularly important because they support information exchange, education, training, public engagement, social learning, behavioural change, and stakeholder participation (Ernsteins et al., 2017a). This concept is especially relevant in water governance, where water crises are increasingly recognised as governance failures resulting from fragmented, ineffective, and insufficiently inclusive decision-making processes rather than solely from resource shortages (OECD, 2011; Ernsteins et al., 2025).

The aim of this study is to analyse and compare environmental and water governance in local territorial systems in Latvia, including municipal statutory governance systems and small river basin territories that are not formally integrated into mandatory municipal planning frameworks. The purpose is to identify opportunities for more integrated, adaptive, and participatory governance.

To examine environmental governance under different territorial conditions, the study applies the triple governance dimensions framework to three contrasting cases in Latvia: Kekava Municipality, representing a comparatively advanced peri-urban municipality; the Dviete River Basin, representing a small river basin SES largely within a single municipality; and the Lake

Lubans Basin, representing a complex multi-municipal lake–wetland SES. Together, these cases enable comparison of governance across administrative and socio-ecological territorial settings.

Materials and Methods

This study employed a comparative case study design to analyse environmental governance across three territorial cases in Latvia: Kekava Municipality, the Dviete River Basin, and the Lake Lubans Basin. The cases were selected to represent different socio-ecological and governance contexts, ranging from a comparatively advanced peri-urban municipality (Kekava) to a small river basin system largely situated within a single municipality (Dviete River) and a complex multi-municipal lake–wetland SES (Lake Lubans). Together, these cases provide an opportunity to compare environmental governance under different territorial and institutional conditions.

The study applies the Triple Governance Dimensions framework (Ernsteins et al., 2017a, 2017b), which conceptualises environmental governance through three complementary dimensions: governance content (what) - environmental governance sectors and SES components; governance stakeholders (who) - actors involved in governance processes; and governance instruments (how) - mechanisms used to implement governance objectives.

Particular attention was devoted to governance instruments, including policy and legislative, planning, institutional and administrative, economic and financial, infrastructure and technological, and communication and collaboration instruments (Ernsteins et al., 2017a; Konkovs & Ernsteins, 2020). Governance content was analysed using an SES perspective, while stakeholder analysis focused on identifying the principal stakeholder groups participating in governance processes.

The comparative case study design was chosen to analyse how environmental governance is organised and practised across territorially different socio-ecological contexts while using a shared analytical framework. The three cases: Kekava Municipality, Lake Lubans, and the Dviete River Basin, were selected because each represents a distinct territorial governance setting and a different combination of environmental issues, governance arrangements, and stakeholder constellations, yet all can be examined through the same Triple Governance Dimensions framework.

Across all three cases, the methodological approach combined qualitative case study research with a research-and-development orientation. A common research logic was applied in each case: to assess governance arrangements at different administrative levels, analyse relevant policy, planning, and management documents, identify the stakeholder groups involved, and evaluate the use and complementarity of governance instruments. Accordingly, the empirical strategy relied on a combination of document analysis, field-based inquiry, and stakeholder interviews. In each case, the territorial unit was viewed as an SES, and the analysis sought to capture both formal governance arrangements and actual management practices.

To support comparative assessment, a SWOT (Strengths, Weaknesses, Threats and Opportunities) analysis was conducted for all three case studies. The SWOT framework was structured around the three governance dimensions and examined strengths, weaknesses, opportunities, and threats related to governance sectors, governance stakeholders, and governance instruments. This enabled a systematic comparison of governance performance across the selected territorial cases.

In the Lake Lubans case, the empirical work relied heavily on interviews and field inquiry. In total, 45 face-to-face interviews were conducted through visits to organisations and institutions in Rezekne and Madona municipalities, especially in Nagli, Gaigalava, Barkava, and Osupe parishes. These site visits also included observations at relevant locations in the field, enabling the researchers to relate stakeholder perspectives to the territorial context. Following the fieldwork stage, 27 additional remote interviews were conducted, including short express interviews lasting approximately 10–15 minutes. The questionnaire was organised into four thematic blocks: (1) introduction and respondent profile in relation to stakeholder representation; (2) perceptions of Lake Lubans as an SES and of the population and professional groups connected to it; (3) values associated with Lake Lubans and its surrounding territory and (4) management problems and governance of Lake Lubans, including all six groups of governance instruments as well as governance sectors and stakeholder groups. Overall, the Lake Lubans case covered finterviews with five main stakeholder groups and assessed the governance system of the lake through the triple governance dimensions framework.

In the Dviete River Basin case, the study applied an integrated case study methodology developed within the BLIFE and OPTAIN project frameworks. The case was selected because of its distinctive combination of natural values, cultural landscape, and bottom-up governance experience. The analysis proceeded through several interrelated steps: environmental governance audit, environmental communication audit, municipal monitoring audit, stakeholder mapping and consultations, assessment of the multi-stakeholder MARG process, and complementary in-depth semi-structured interviews. First, governmental, municipal, and research databases were reviewed. This was followed by an analysis of legal, policy, and planning frameworks at the national, regional, and local levels. Particular attention was paid to municipal statutory and voluntary planning documents, including the Sustainable Development Strategy, Development Programme, Spatial Plan, Environmental Report, and Monitoring Report of the former Ilukste Municipality,

as well as subsequent documents produced by the newly established Augsdaugava Municipality after the 2021 territorial–administrative reform. These analyses were complemented by field visits, photo documentation, and stakeholder interviews.

An additional component of the Dviete methodology was stakeholder mapping and engagement conducted within the OPTAIN project. Using the Quintuple Helix Stakeholders Constellation and Collaboration Model, stakeholders were identified and grouped into five meta-groups: the state, municipalities, businesses, society, and mediators (Ernsteins et al., 2017a, 2017b). In total, 50 stakeholder organisations were mapped: the state (8), municipalities (10), businesses (6), society (5), and mediators (21). On the basis of this mapping, a Multi-Actor Reference Group (MARG) was established as a collaborative platform for local and regional water retention assessment and planning. Three annual MARG meetings were organised, each involving 10–12 participants representing the identified stakeholder groups, and action research elements were used to facilitate and analyse the process. Finally, 21 in-depth semi-structured interviews were conducted, mostly in person, with representatives of all stakeholder groups: state agencies (3), municipalities (5), businesses (3), society (2), and mediators, including NGOs, the media, educators, and academic actors.

The Kekava Municipality case was analysed using the same comparative methodological framework. The assessment applied the triple governance dimensions framework and examined governance content, governance stakeholders, and governance instruments. Data collection included analysis of municipal governance documents, environmental planning materials, stakeholder involvement practices, and governance implementation mechanisms. Applying the same analytical framework across all three cases ensured methodological consistency and enabled direct comparison between different territorial governance contexts.

Overall, the comparative case study design enabled analysis of environmental governance across three distinct SESs while maintaining a common analytical structure. The approach facilitated comparison of governance arrangements, stakeholder participation, governance instruments, and governance content, providing a basis for identifying common patterns, governance challenges, and opportunities for strengthening integrated and participatory environmental governance in Latvia.

Results and Discussion

The Results section presents the findings of environmental governance audits carried out in three contrasting territorial cases in Latvia: the Dviete River Basin, the Lake Lubans Basin, and Kekava Municipality. Using a common analytical framework, the section examines each case through three interrelated governance dimensions - governance instruments, governance sectors, and governance stakeholders - while also incorporating a SWOT perspective to synthesise the main strengths, weaknesses, opportunities, and threats. The purpose is to identify how environmental governance is structured and functions in different administrative and socio-ecological contexts, and to highlight similarities and differences in governance maturity, integration, coordination, and capacity across the selected cases.

National and local frameworks for environmental and water governance

Latvia's legal framework requires municipalities to manage the environment through a comprehensive but fragmented system of laws and governance instruments that define their functions, planning duties, financing options, and cooperation with the public. Municipal environmental governance is organised around six groups of instruments - legal and political, planning, economic and financial, institutional and administrative, infrastructure and technology, and communication - and local governments, as public law entities may act only on the basis of regulatory enactments that specify their environmental functions, rights, and duties.

Key acts are the Law on Local Governments, the Environmental Protection Law, the Law on Spatial Development Planning, and regulations on local government development planning documents, which together regulate both the content and procedures of municipal environmental governance. The Law on Local Governments (in force since 2023) sets autonomous environmental functions, including organising water, heating, and municipal waste management; maintaining public areas and green spaces; promoting the sustainable management of natural capital; and contributing to climate change mitigation and adaptation.

Municipal environmental governance is to be integrated into three statutory planning documents - the Sustainable Development Strategy, the Development Programme, and the Spatial Plan - which must conform to national strategies and policy guidelines, while municipalities may also prepare additional sectoral plans (e.g., on energy, climate, mobility, or waste). In the financial field, municipalities work within their own budget and a special budget formed from natural resources tax revenues, which may be used only for environmental protection measures. They also rely on EU and national financial instruments for larger investments in climate and environmental projects.

Institutionally, municipalities must ensure basic environmental utilities, but the internal administrative structures responsible for environmental governance differ widely between municipalities, ranging from dedicated departments to individual specialists or shared responsibilities. Environmental governance also covers infrastructure systems such as centralised water supply, sewerage, treatment plants, and landfills, where eligibility for external funding is often linked to

innovative, energy-efficient solutions. Communication instruments based on constitutional and environmental law guarantee the public's right to environmental information and participation in planning through consultations and public involvement.

In Latvia, water resources governance follows a multi-level governance approach, in which responsibilities are divided between state institutions, municipalities, and other stakeholders in line with the Water Management Law (Parliament of the Republic of Latvia, 2002) and related regulations. The Water Management Law establishes the institutional framework for river basin management, monitoring, planning, and public participation, coordinated by environmental authorities, including the Latvian Environment, Geology and Meteorology Centre. The Land Management Law (The Parliament of the Republic of Latvia, 2014) allocates holding rights over inland public waters and coastal areas between the environmental ministry, local governments, and private owners, and defines when municipalities act on behalf of the owner in authorising activities in public waters.

Municipalities, as stipulated by the Local Government Law (The Parliament of the Republic of Latvia, 2022), possess both rights and responsibilities concerning water governance. These encompass the organisation of water services, the facilitation of territorial development, the maintenance of sanitary conditions, and flood protection, and the advancement of sustainable natural resource management and climate change adaptation. Within their administrative boundaries, municipalities are tasked with the organisation of public water services, which may be executed through municipal institutions or delegated to entities such as municipal capital companies. Despite these delegations, municipalities retain ultimate accountability for legal compliance and service quality. Furthermore, they are empowered to engage residents through consultative councils and the mandatory participatory budget, as mandated by the Local Government Law. This budget, which allocates a minimum of 0.5% of designated tax revenues, enables local communities to propose and vote on projects pertaining to water infrastructure, flood risk mitigation, and coastal management.

Environmental governance audit in the Kekava Municipality

Kekava Municipality is located near Riga, covers 443.91 km² and has about 32,000 inhabitants. Its main natural resources include forests (about half of the territory), the Daugava River, smaller rivers, and Lake Titurga. Key environmental challenges involve maintaining environmental quality for living and working, ensuring access to public green spaces, supporting tourism, limiting polluting industries, and promoting local agriculture and crafts. The 2025 municipal budget is about EUR 91 million, with EUR 0.27 million allocated to environmental measures.

Environmental governance is relatively well-developed and guided by planning documents. Environmental specialists are integrated within the Municipal Property Management Department, ensuring cross-sectoral coordination. The municipality's vision aims to ensure a high-quality living environment, particularly for families.

Environmental governance instruments

Environmental governance is supported by a diverse set of instruments. Political instruments include party programmes that prioritise energy transition, mobility, and green infrastructure.

Legislative and planning instruments align with national frameworks and include documents such as the Sustainable Development Strategy 2030, the Development Programme 2021-2027, the Investment Plan, and the Spatial Plan. These voluntary initiatives, such as GMO restrictions, the Territory Improvement Plan, the Energy and Climate Action Plan, and the Hogweed Control Plan, complement these efforts.

Economic instruments are based on the municipal budget and additional revenues such as the Natural Resources Tax. Funding supports environmental education, biodiversity, climate action, water and soil protection, waste management, and restoration.

Institutional instruments rely on a structured administration with embedded environmental expertise, supported by interdepartmental cooperation and project-based working groups. Infrastructure-related instruments reflect regional cooperation - for example, wastewater treatment in Riga, shared water supply, and waste disposal at the Getlini landfill.

Communication instruments include public consultations, streamed council meetings, and active use of social media platforms to engage residents.

Overall, governance effectiveness depends on the interaction of sectors, stakeholders, and instruments, enabling the municipality to address challenges such as mobility, energy transition, and waste management.

Environmental governance content (sectors)

Environmental governance covers both traditional and cross-sectoral areas. Core sectors include water management (supply, wastewater, and surface waters), waste management, and district heating.

The municipality integrates cross-sectoral activities such as energy efficiency, renewable energy transition, and sustainable mobility. Landscape planning and unified territorial design systems are also developed.

Green infrastructure management (forests, parks, and riverbanks), land melioration, rainwater drainage, and maintenance of natural areas are key activities. Biodiversity conservation, environmental protection, and education further complement these sectors.

Implementation is ensured by specialists within the Municipal Property Management Department, including environmental, forestry, landscape, and melioration experts, who contribute to planning documents and project development.

Environmental governance stakeholders

A broad range of stakeholders is involved. Cooperation with state institutions (ministries and environmental authorities) and neighbouring municipalities (Riga, Marupe, Olaine, Salaspils, and

Bauska) is essential, particularly for shared infrastructure and services.

The private sector is engaged through the Business Council, tax incentives, and support for local producers (e.g., 'Made in Kekava'). Civil society participates through NGO co-financing, joint initiatives, and regional partnerships. The public is involved via consultations and participation processes. Within the municipality, governance is led by the Municipal Property Management Department, supported by other departments and supervised by the Council and its committees. Working groups address specific issues and include external experts. Municipal companies provide key services such as water, wastewater, heating, and territory management.

The municipality also participates in international networks, such as the INTERREG URBACT project 'CITIES4CSR', which promotes social responsibility.

SWOT analysis: governance system framework

Before presenting the SWOT analysis, it is important to note that the findings results provide a holistic view of the strengths and limitations of environmental governance in Kekava Municipality. The SWOT framework (Table 1) serves as a synthetic analytical instrument that helps structure the key findings across the three examined dimensions - governance instruments, sectors, and stakeholders - by identifying internal capacities and constraints, as well as external development opportunities and risks. This approach allows a clearer understanding of the municipal administration's current performance while also highlighting priority areas for future improvement and strategic development in environmental governance.

Table 1

SWOT analysis of strength and weaknesses: environmental governance in the Kekava Municipality

Strengths	Weaknesses
Sectors. Environmental governance is integrated across sectors including forestry, water resources, energy efficiency, and landscape planning. Specialist positions for forestry, melioration, and environment are embedded within the municipal property department to ensure coordination. **Instruments.** The municipality utilizes statutory documents and voluntary initiatives (Energy and Climate Action Plan, GMO prohibition). Institutional branding and territorial signs are used as instruments to promote the local environment. Financial autonomy, participatory budget. **Stakeholders.** Cooperation with the Business Council, local NGOs via co-financing projects. The municipality serves as a primary environmental link between national institutions and the local society. Active stakeholder engagement and communication including with inhabitants.	**Sectors.** The transition to renewable energy within the private household and industrial sectors remains a significant challenge. There is an identified internal need for more effective waste reduction strategies across municipal sectors. Insufficient coordination of measures with neighbourhood municipalities and state institutions, scientifical institutions. Fragmentation in cross-sector coordination. **Instruments.** Current governance instruments insufficient for high-level goals in sustainable mobility. Policy implementation regarding the transition from fossil fuels requires more robust management mechanisms. Limited budget for direct environment improvement purposes and public involvement activities. **Stakeholders.** The governance system lacks broad, active involvement of researchers, local grassroots communities. Interaction with specific private sector segments regarding energy transition is still in development.

Kekava: triple governance dimensions

Sectors. Sectoral governance demonstrates a high level of integration, combining environmental governance areas such as forestry, water resources, energy efficiency, and spatial planning, and is supported by embedded specialist roles within the municipal structure. However, significant challenges remain in advancing renewable energy adoption and implementing effective waste reduction strategies, indicating gaps between strategic integration and practical implementation. The sectoral dimension is characterised by strong integration and alignment with environmental priorities, providing a solid foundation for sustainable development. Opportunities such as eco-tourism and scientific innovation can further strengthen this system. However, external pressures, including industrial pollution and climate change, as well as internal challenges related to energy transition and waste management may hinder progress. Strengthening capacity and resilience is essential.

Instruments. The municipality employs a diverse set of governance instruments, including both mandatory planning frameworks and voluntary initiatives, complemented by branding instruments that enhance environmental awareness and territorial identity. Despite these efforts, the existing instruments are insufficient to fully achieve sustainability goals, particularly in sustainable mobility and the transition away from fossil fuels, because of limited implementation capacity and the lack of robust mechanisms. The governance framework includes a combination of regulatory and voluntary instruments, creating a flexible basis for sustainability policies. External funding opportunities and methodological instruments can significantly improve governance effectiveness. Nevertheless, financial constraints, complex national regulations, and insufficiently developed instruments limit the municipality's ability to achieve ambitious goals. A more coherent, better-funded, and implementation-oriented instrument system is needed.

Stakeholders. Stakeholder engagement is supported through active cooperation with business organisations and NGOs, with the municipality effectively acting as a mediator between the national and local levels. At the same time, engagement remains incomplete, with insufficient involvement of researchers, grassroots communities, and certain private-sector group, particularly in the context of the energy transition. Stakeholder cooperation is relatively well-developed at the institutional and organisational levels, with potential to expand through international partnerships and intermunicipal collaboration. However, limited inclusiveness and external economic and political pressures weaken stakeholder engagement and autonomy. Broadening participation and strengthening local capacity are key to ensuring sustainability.

Overall conclusion on the governance system. The governance system demonstrates a comparatively high level of integration and strategic orientation toward sustainability, supported by diverse instruments and municipal institutional cooperation. However, its effectiveness is constrained by implementation gaps, limited stakeholder inclusiveness, and external pressures such as financial restrictions, regulatory complexity, and environmental risks.

Environmental governance audit in the Dviete River basin

The Dviete River Basin represents a territorially distinctive SES in which environmental governance is shaped by the interaction of protected natural values, agricultural land use, floodplain dynamics, local community practices, and limited formal governance capacity. As part of the Natura 2000 network, the basin is characterised by valuable habitats, cultural heritage, and the growing importance of participatory approaches. However, governance remains fragmented, with responsibilities distributed across the national, regional, and local levels without a coordinated system, leading to inefficiencies in decision-making and environmental governance.

The environmental governance audit was structured around three dimensions - governance instruments, sectors, and stakeholders - and focused on water resources, environmental protection, and socio-economic development, with environmental communication as a cross-cutting component.

The results show that governance in the basin is institutionally present but operationally weak. While a broad set of instruments, sectors, and actors exists, their interaction remains limited. Vertical coordination between governance levels is insufficient, horizontal integration across sectors is uneven, and local bottom-up initiatives often compensate for the lack of long-term administrative capacity. Thus, governance is present but requires stronger complementarity, continuity, and collaboration to ensure effectiveness.

Environmental governance instruments

The audit identified a broad spectrum of governance instruments, including political, legislative, institutional, planning, financial, infrastructural, and communication instruments. However, despite this formal completeness, their implementation remains fragmented and weakly coordinated.

The main challenge lies not in the absence of instruments but in their limited integration and inconsistent application. Responsibilities are distributed across institutions with overlapping competences, complicating implementation.

Political and regulatory instruments, such as Natura 2000 regulations and the Dviete Nature Park framework, provide a strong legal basis. However, the absence of a stable, long-term management structure limits their effectiveness. As a result, legal provisions are not consistently translated into practice, leading to ineffective conservation management.

Institutional capacity is constrained, especially at the local level. Cooperation between institutions is often weak, with actors operating within separate domains. Differing priorities and limited information exchange further reduce implementation effectiveness, particularly in water governance.

Planning instruments are formally well-developed but insufficiently operationalised. Strategic documents define long-term objectives, but lack effective monitoring, feedback, and implementation mechanisms. Key issues such as water retention and cross-sectoral coordination remain only partially integrated.

Financial instruments rely heavily on short-term project funding, municipal budgets, and conservation investments. Although these sources support restoration and ecotourism, funding instability limits long-term capacity. The lack of stable financing reduces conservation effectiveness and results in insufficient infrastructure and technological capacity.

Infrastructure and technological instruments are critical because of floodplain conditions but remain underdeveloped. Outdated drainage systems and insufficient river maintenance increase environmental risks, reflecting both technical and governance gaps.

Communication instruments are comparatively stronger, and include digital platforms, tourism materials, and educational activities. Local NGOs and the Dviete Valley Information Centre play key roles. However, communication is uneven across sectors and depends largely on local initiatives rather than on systematic institutional support. Overall, despite a comprehensive formal framework, governance instruments remain weakly integrated and lack long-term coordination.

Environmental governance sectors

Governance in the basin extends beyond nature protection to include water management, environmental protection, and socio-economic development, yet these sectors remain poorly integrated.

Water governance is both critical and weak. Despite its importance, local implementation capacity is limited. Monitoring exists, but communication and management measures are insufficient. The lack of

coordinated management contributes to environmental risks, indicating that local water governance remains underdeveloped.

The environmental protection sector is comparatively stronger because of the Natura 2000 and biodiversity conservation frameworks. The Nature Conservation Agency plays a central role, supported by NGOs and local actors. However, reliance on project-based and voluntary efforts limits long-term sustainability.

The socio-economic sector reflects the basin's dual role as both a protected and a productive landscape. Agriculture is economically important but exerts pressure on water quality and biodiversity. Ecotourism potential is significant but not yet fully integrated with environmental objectives. Weak coordination between sectors limits sustainable development. Overall, sectoral fragmentation persists, with relatively strong environmental protection, weak water governance, and limited integration across sectors.

Environmental governance stakeholders

The stakeholder landscape is diverse but weakly connected. State institutions provide regulatory and monitoring functions but are often perceived as distant, with limited involvement in local problem-solving. Municipalities play a central role but face significant constraints.

Business actors, particularly farmers and tourism providers, influence land use but are insufficiently integrated into governance processes. This contributes to conflicts and limits sustainable resource management.

Societal actors participate in governance, but their engagement is uneven and often depends on individual initiative rather than on structured mechanisms.

NGOs, especially Dviete Valley organisations, play a critical mediating role by undertaking functions such as biodiversity management, communication, and coordination. While this reflects strong local engagement, it also indicates structural weaknesses, as governance relies heavily on voluntary, project-based efforts.

Overall, although many stakeholders are present, their interaction remains limited. Strengthening coordination, communication, and trust-building is essential for more integrated and effective environmental governance in the Dviete River Basin.

SWOT analysis: governance system framework

The SWOT analysis (Table 2) confirms that the Dviete River Basin possesses strong natural, cultural, and social assets, including Natura 2000 status, biodiversity value, active local initiatives, and ecotourism potential. At the same time, governance weaknesses, such as fragmented institutional structures, insufficient funding, outdated infrastructure, and weak sectoral integration, limit the effectiveness of environmental governance.

Internal opportunities include improved use of EU funding, strengthened local governance capacity, and better sectoral integration. However, threats such as climate change, flooding, depopulation, and continued institutional fragmentation pose significant risks.

Overall, the results demonstrate that the Dviete River Basin has a solid governance foundation but lacks the integration, coordination, and long-term capacity required for effective environmental governance. Strengthening both vertical and horizontal integration, as well as supporting local participatory actors, will be essential for future development.

Dviete: triple governance dimensions

Sector dimension. The sector dimension shows a development base in certain areas, such as waste management and environmentally adaptive sectors (organic agriculture and tourism), indicating the system's capacity for adaptation. The sector dimension is significantly constrained by outdated environmental infrastructure, which increases environmental risks and limits effective resource management. The sector dimension, despite the development potential of certain sectors (e.g., environmentally friendly agriculture and tourism), is significantly constrained by outdated infrastructure and conflicting interests; however, its development can be supported by growing demand for ecotourism and the availability of EU funding, while being threatened by climate change, invasive species, and increasing economic pressure on natural resources.

Instruments dimension. The instrument dimension is strengthened by an established planning and monitoring system with a regulatory framework, providing in general a structured approach to environmental governance. The instrument dimension is weakened by having comparatively complex and formal planning documents with low implementation levels, as well as a strong dependence on short-term project funding. The instrument dimension is characterised by a formally established and structured plan; however, its effectiveness is limited by implementation challenges and dependence on short-term funding. Development opportunities exist in EU programmes and innovation in governance instruments, but their effectiveness is also limited by implementation challenges and dependence on short-term funding, while development opportunities lie in EU programmes and innovation in governance instruments; at the same time, it is threatened by inconsistent state policies and the risk of failing to meet international environmental targets.

Stakeholders dimension. The stakeholder group dimension benefits from high expert competence and some active involvement of NGOs, ensuring/assisting the practical implementation of environmental governance. The stakeholder's dimension is limited by weak cooperation, lack of trust, and insufficient capacity, which restrict effective participation and governance. The stakeholder's dimension is strengthened by high expert capacity and active NGO involvement but constrained by weak cooperation, low public participation, and limited capacity, while its development potential lies in cooperation with

scientific institutions and advancing participatory mechanisms; however, it is threatened by low environmental awareness, depopulation, and conflicts between landowners and environmental objectives.

Table 2

SWOT analysis of strength and weaknesses: environmental governance in the Dviete River basin

Strengths	Weaknesses
Sectors. Overall statutory sectorial planning, relatively developed waste management system. Ability of certain sectors (organic agriculture, tourism) to adapt to environmental requirements. Established environmental monitoring and data system, including digital instruments for load/violation analysis. Developed local nature and tourism infrastructure (nature trails, viewing towers, infostands, birdwatching towers). Part of the Natura 2000 network. Unique habitats and high biodiversity value. Rich cultural history and landscape value. Strong ecotourism potential. **Instruments.** Developed Municipal Statutory planning system, including monitoring system, with regulatory framework and general data instruments. Good availability of environmental information at local level through local media and portals. Organised waste sorting and collection infrastructure and residents' habits to use it. Cooperation between municipalities and science in implementation of research projects. Established economic and financial instruments, including environmental taxes, subsidies and project-based EU funding schemes. Use of consult-first administrative practices that prioritise guidance and voluntary compliance over punitive sanctions. Existing communication and education initiatives, including the 'Gulbji' centre. **Stakeholders.** High level competence, project involvement Active NGOs, local leaders for practical management. Self-organization/participation potential: communities. Practical experience of businesses and NGOs in maintaining the territory (river cleaning, maintenance of drainage ditches, maintenance of nature infrastructure). Businesses adaption: organic farming, ecotourism.	**Sectors.** Outdated infrastructure and data gaps Overgrown riverbeds, insufficient regular river cleaning, leading to waterlogged floodplain areas Lack of professional specialists in municipalities for cultural heritage and research issues. Conflicts between nature protection requirements in protected areas and the practical needs of agricultural land use, including restrictive regimes and low compensation levels for farmers. Limited financial support. Agricultural pressure on groundwater and surface water. Potentially polluted sites in the basin. **Instruments.** Formal planning documents – limited implementation, monitoring. Institutional fragmentation and weak cross-sectoral cooperation. Insufficient capacity and shortage of specialists. Dependence on short-term project funding as constantly limited municipal budgetary funding for any development programms and projects. Public receives limited and mainly formal top-down communication, resulting in insufficient, poorly targeted information. **Stakeholders.** Weak and formal communication with society. Low and selective public participation. Dependence on voluntary work and individual enthusiasm. Lack of administrative capacity in NGOs and municipalities to perform broad governance functions in the long term. Low public activity in planning/decision-making processes, especially among young people.

Overall conclusion on the governance system. The municipal and river basin environmental governance system is formally established at the municipal level; however, it is functionally fragmented. While there are strengths such as a formal municipal territorial planning framework, overall municipal development in certain sectors, and some expert competence, these are insufficient to compensate for structural weaknesses. As a result, the system operates more reactively than strategically and is heavily dependent on municipal capacities, particularly administrative and financial resources.

Environmental governance audit in the Lake Lubans basin

Lake Lubans is one of the most complex environmental governance cases in Latvia, and requires an integrated, cross-sectoral approach. As Latvia's the largest lake and part of a broader wetland system, it constitutes a SES shaped by long-term human intervention, including water regulation and infrastructure. Governance must therefore extend beyond the lake itself to the surrounding ecosystems, infrastructure, and socio-economic activities. However, governance has been hindered by the late adoption, in 2024, of a comprehensive wetland protection plan, resulting in fragmented and inconsistent management.

Although it is part of Natura 2000, the lake long lacked a clear framework for balancing protection and development. Restrictions were introduced without an integrated strategy, creating tensions between conservation objectives, local livelihoods, and economic interests. The analysis is structured around three dimensions: sectors, stakeholders, and instruments.

Environmental governance instruments

A wide range of governance instruments exists, including political, legislative, institutional, planning, economic, infrastructural, communication, and collaborative instruments. However, their development and application remain uneven.

Political and legislative instruments, including the Natura 2000 and Ramsar frameworks, provide strong regulatory foundations but often create tensions by restricting local development. Institutional instruments involve key actors, but coordination remains limited.

Planning instruments are relatively weak because comprehensive strategies were only recently developed, contributing to fragmented governance. Economic instruments (taxes, permits, funding mechanisms) exist but are not aligned with integrated lake development.

Infrastructure and technological instruments are critical because of the regulated water system but remain underdeveloped and poorly maintained. Communication instruments exist but remain fragmented, with unclear information and limited stakeholder engagement. Collaborative instruments, such as NGOs and community initiatives, are weakly integrated into the overall governance system.

Overall, although all instrument groups are present, weak planning, coordination, and communication limit effective governance and prevent the lake from being managed as a coherent SES.

Environmental governance content (sectors)

Governance content in Lake Lubans extends beyond the lake itself to include wetlands, infrastructure, and the surrounding territories. The absence of a unified governance plan has reduced clarity regarding priorities and slowed implementation, contributing to fragmented and inefficient management.

Governance is currently dominated by three clusters: nature protection, tourism and recreation, and economic activities (mainly fishing and agriculture). However, a broader SES perspective encompasses governance, environmental protection, natural resources, economic activities, recreation, education, culture, and waste management.

The governance sector includes municipalities, state institutions, NGOs, and local initiatives, but it is increasingly dominated by municipalities because of declining civic engagement. Nature protection is the strongest sector, driven by strict conservation rules within the Natura 2000 wetland system. However, restrictions introduced without clear development strategies have negatively affected local economies and shaped negative perceptions of governance.

Key environmental challenges include overgrowth, wetland expansion, pollution, reed spread, invasive species, and flooding. Bird protection is significant but creates conflicts with agricultural interests.

The environmental protection sector encompasses the regulation of natural resources, fishing, hunting, and pollution. It is essential but conflict-prone, because restrictions often limit economic activities. Waste management remains insufficiently integrated, with persistent issues of littering and illegal dumping.

Recreation and tourism remain underdeveloped despite their strong potential. Activities such as fishing, hunting, and nature tourism are present but remain poorly integrated into governance. Tourism remains seasonal and limited in diversity, with substantial untapped potential in cultural and sustainable tourism.

The social sector supports community life, culture, and education, although its integration with lake governance remains partial. The economic sector (agriculture, fisheries, forestry, tourism) is constrained by environmental restrictions and declining productivity.

Overall, governance is unbalanced: nature protection dominates, while the economic, social, and recreational sectors remains weaker and insufficiently integrated.

Environmental governance stakeholders

Stakeholders include state institutions, municipalities, businesses, mediators, residents, and tourists, each with diverse and sometimes conflicting interests.

State institutions (e.g., the Nature Conservation Agency and the State Environmental Service) provide regulatory and monitoring functions but lack strong integration. Municipalities (Madona and Rezekne) play key roles in local management but face coordination challenges because of the absence of a clear governance framework.

Business actors, including farmers, fish farms, and tourism providers, are economically important but remain weakly integrated into governance. Local residents are also underrepresented despite their historical connection to the lake.

Tourists represent an important but underutilised group, while mediators (NGOs, educators, experts) have strong potential but limited involvement.

Overall, governance is characterised by weak stakeholder integration, limited communication, and conflicts of interest. State and municipal actors dominate, while other groups remain underengaged.

SWOT analysis: governance system framework

The SWOT analysis (Table 3) shows that Lake Luban governance has a solid foundation, supported by multi-sectoral cooperation, strong local environmental awareness, and a development vision focused on nature tourism. However, it is constrained by fragmentation, weak stakeholder involvement, and insufficient coordination, which can lead to ineffective decision-making and hinder the implementation of sustainable practices. The region also offers opportunities, such as access to EU funding and the growth of nature tourism under relatively low environmental pressure. At the same time, risks including stakeholder conflicts, climate change, and infrastructure pressures may further hinder sustainable and integrated governance.

Table 3

SWOT analysis of strength and weaknesses: environmental governance in the Lake Lubans basin

Strengths	Weaknesses
Sectors. Governance is dominated by nature protection and Natura 2000 status. Educational institutions introduce environment. Systematic fish resource restoration is carried out. Unique inland fishing traditions in Idena village. **Instruments.** The sluice system provides full water level control. Municipalities own tourism information centres. The water tourism centre 'Baka' is operational. Political/legal regulation of fishing net leases. The Wetland Information Centre is a key nature centre in the Lubana region. Tourism as a regional development instrument. **Stakeholders.** Municipalities act as the main intermediaries between institutions and residents. Local specialists perform daily management tasks. Citizen Advisory Councils have been established in the Rezekne district. Local hunting and angling clubs are active. Lubana Lake region is popular among bird watching groups and nature tourism groups. Local tourism and recreation-related business owners benefit from the lake and territory development plans.	**Sectors.** Sectoral governance is fragmented and uncoordinated. The socio-economic and tourism sectors are underdeveloped. Lack of sufficient waste management control on the coast. No companies in the region process lake reeds. **Instruments.** Missing lake-wetland management plan. Insufficient communication, involvement instruments. Recreation infrastructure and the road network are worn. Information maps regarding nature objects and recreation sites are lacking. The Lubana Wetland Information Center is the only nature information center in the region. Financial instruments are limited and underused. **Stakeholders.** Residents are not sufficiently involved in decision-making. Entrepreneurs receive weak institutional support. Limited cooperation: state institutions and municipalities. Interests of hunters and anglers are poorly represented in planning documents. Environmental activists are divided regarding nature conservation and lake water levels. All types of stakeholders have conflicts of interest regarding the development of the region.

Lubans: triple governance dimensions

Sectors. Sectoral development is strongly rooted in nature protection, with the active involvement of educational institutions and the preservation of traditional practices, thereby supporting ecological sustainability and cultural continuity. However, sectoral governance is fragmented, with weak integration of socio-economic and tourism development, insufficient environmental control, and limited value-added economic activity. The sectoral dimension shows a strong environmental orientation and substantial cultural value, but its long-term sustainability depends on better integration with economic sectors. Opportunities such as eco-tourism, innovation, and bioresource use could significantly enhance development, yet they are constrained by environmental degradation, economic decline, and climate-related pressures. A more balanced and coordinated sectoral approach is essential.

Instruments. Existing instruments provide a solid technical and regulatory foundation, particularly in water-level management, tourism support infrastructure, and legal frameworks for resource use. At the same time, he lack of strategic planning, insufficient communication instruments, outdated infrastructure, and missing informational resources limitseffective governance and public engagement. The instrument framework has a functional base but lacks strategic coherence and modernisation. External funding opportunities and new planning initiatives could substantially strengthen governance capacity. However, institutional complexity, insufficient funding, and regulatory constraints pose significant risks. Developing a unified management system and improving infrastructure and communication instruments are critical priorities.

Stakeholders. Local stakeholders, especially municipalities and community organisations, play an active role in daily management and serve as important intermediaries between institutions and residents. Nevertheless, stakeholder involvement is uneven, with low participation by residents, weak support for entrepreneurs, limited institutional cooperation, and under-representation of key interest groups in planning processes. Stakeholder engagement is locally grounded but insufficiently inclusive and coordinated. There is strong potential to expand cooperation with scientific institutions, NGOs, investors, and international visitors, which could drive innovation and economic growth. However, social and environmental pressures, including emigration, pollution, and unmanaged tourism, threaten stakeholder cohesion and long-term participation. Strengthening collaboration and inclusion is essential.

Overall conclusion on the governance system. The governance system is characterised by a strong focus on environmental protection, supported by dedicated local actors. However, it suffers from a lack of integration, coordination, and strategic alignment across sectors, instruments, and stakeholders. This fragmentation undermines the effectiveness of governance structures, limits stakeholder involvement, and hampers innovation and the development of nature tourism and recreation. Additionally, external

environmental and economic threats pose further challenges. To ensure long-term sustainability, it is essential to establish a structured and participatory governance system based on a unified management approach. This should include new forms of institutional cooperation with a local administrative presence or, at minimum, consultation and communication structures, such as a Wetland Communication Centre. It is also important to apply a complementary planning approach that encompasses all governance instruments while ensuring a balanced integration of ecological, economic, social, and managerial priorities.

Municipal environmental and water governance developmental status and practice limitations

A relatively well-established legislative and institutional framework generally shapes environmental governance in Latvian municipalities. Local governments and municipalities operate within a national system that defines environmental responsibilities, planning requirements, and governance instruments such as spatial planning, environmental protection regulations, and public participation procedures. This results in a moderately developed municipal governance structure where environmental issues are formally addressed, although their integration into broader municipal development planning remains incomplete and uneven across territories (Ozolins et al., 2023). Administrative capacities have improved, particularly after the administrative-territorial municipal aggregation reform, yet they still vary significantly between municipalities and depend on local available resources and institutional arrangements, according to each municipality's traditions and decisions. At the same time, municipal environmental governance faces key challenges in cross-sectoral integration, coordination, and stakeholder engagement, hindering effective policy implementation and sustainable development.

Environmental governance empirics: summaries from municipal and water basin case studies

Latvia's environmental and water governance is characterised by a relatively comprehensive, although fragmented, legal structure, also oriented towards harmonising national objectives with municipal implementation. Local authorities are instrumental in implementing environmental duties, spatial planning, and sustainable resource management, as also stipulated by the Law on Local Governments; however, because municipalities exhibit institutional and financial inequalities, the system requires stronger multi-level coordination, clearer legal responsibility, and more robust public engagement practices.

The Kekava Municipality case confirms that the three-dimensional environmental governance model, linking governance instruments, stakeholders, and sectors, provides a coherent framework for integrating environmental objectives into local development practice. The interaction between a diverse set of instruments, a broad and actively involved stakeholder network, and an expanding sectoral scope enables more coordinated, cross-cutting, and participatory decision-making, while also revealing the need for continuous capacity-building and monitoring to ensure that this integrated model is fully operationalised in everyday municipal governance.

The Dviete River Basin case demonstrates that the three-dimensional environmental governance model reveals a clear mismatch between formal design and practical functioning: although a broad mix of instruments, sectors, and stakeholders is present, their interactions remain weak, fragmented, and only partially coordinated. Governance instruments are formally diverse but insufficiently complementary, sectoral governance is uneven, with water management particularly underdeveloped, and stakeholder networks are active yet weakly interconnected and highly dependent on bottom-up NGO initiatives. As a result, the basin's governance system rests on a structurally solid but operationally fragile foundation, and strengthening vertical and horizontal integration among instruments, sectors, and stakeholders becomes a precondition for moving from fragmented arrangements to integrated river basin governance.

The Lake Lubans case study demonstrates that the three-dimensional governance model reveals a significant disparity among governance content, stakeholder composition, and instrument application: conservation-oriented sectors predominate, stakeholder integration is weak, and essential instruments, particularly those related to planning, communication, and collaboration, are inadequately developed. Although all main sectoral domains are present and a wide range of state, municipal, corporate, community, and visitor groups interact around the lake, their relationships are poorly coordinated, conflicts between conservation and economic use remain largely unresolved, and local residents are only marginally involved in strategic decisions. Similarly, the full set of instrument groups exists in formal terms, but the long-standing absence of a unified wetland governance plan has led to fragmented, reactive, and often contradictory implementation. As a result, Lake Lubans continues to be governed more as a constrained municipal territory than as a coherent SES, making stronger integration across sectors, stakeholders, and instruments a necessary precondition for genuinely sustainable lake governance.

Current and previous research shows that not all environmental issues are sufficiently integrated into municipal planning systems, partly because of limited national-level methodological support and weak public pressure (Ozolins et al., 2023). In addition, communication instruments, such as information provision, public participation, education, stakeholder involvement, and the promotion of pro-environmental behaviour, are often underdeveloped despite general participatory progress, thereby reducing the effectiveness of governance processes. This broader context is essential for interpreting the selected cases,

as even the more advanced example of Kekava Municipality, defined by statutory administrative boundaries, represents a relatively strong case within a still-developing municipal governance landscape.

Comparisons and learning outcomes

The comparison of the three cases: Kekava Municipality, Lake Lubans basin (Aiviekste River basin) and the Dviete River Basin reveals clear differences in the maturity and integration of environmental governance, especially between territories with legal boundaries and those territories defined by socio-ecological criteria. The Kekava Municipality demonstrates the most developed and balanced governance system, with relatively strong institutional integration, broader use of governance instruments, and more structured stakeholder involvement. In contrast, basin-based territorial cases such as Lake Lubans are characterised by fragmented governance arrangements, a lack of unified management planning, and overlapping, potentially conflicting institutional responsibilities between national and local actors (Konkovs et al., 2022). In these territories, especially in Natura 2000 sites, governance is often dominated by nature protection objectives, while socio-economic and participatory dimensions remain insufficiently integrated.

In particular, the Lake Lubans case highlights that governance challenges are strongly linked to the absence of a unified governance approach and management plan, as well as to insufficient stakeholder involvement. Despite the presence of multiple institutions, coordination remains weak, and local communities, businesses, and NGOs are inadequately engaged in planning and decision-making processes (Konkovs et al., 2022); in some Natura 2000 cases, they are almost ignored. This results in a fragmented governance system in which different sectors, such as nature protection, agriculture, tourism, and fisheries, are poorly integrated into local and regional statutory development planning, thereby only weakly reflecting the necessary SES approach.

A common finding across all cases is that governance problems are caused less by the absence of formal instruments than by weak coordination, limited complementarity of instruments, and, especially, insufficient institutional capacity across all administrative levels of governance.

Even where legal frameworks and governance instruments exist, they are not fully implemented in integrated territorial management (Ozolins et al., 2023; Konkovs et al., 2022). This is especially evident in river and lake basin governance, where planning and communication mechanisms for the territory as a whole SES remain underdeveloped.

Sectoral integration differs between municipal and basin cases. Kekava reflects a more integrative, sustainability-oriented approach, increasingly incorporating environmental considerations across sectors. In contrast, Lake Lubans governance remains sector-based, dominated by nature protection with limited integration of economic and social dimensions (Konkovs et al., 2022).

Stakeholder involvement follows a similar pattern: while municipalities such as Kekava have more institutionalised participation mechanisms, basin governance relies more on fragmented, project-based, or weakly coordinated engagement processes. Even in municipalities that include these river basin areas, at least formal-statutory engagement processes are in place.

Towards local developments of system-based and cross-sectoral understanding

The main questions concern the development of two complementary approaches: how to extend the gradually evolving municipal environmental governance practice to river basin territories so that it becomes SES-based territorial governance, and how system-based river basin governance can be effectively integrated into statutory municipal environmental and broader development planning and practice. The main findings from all three case studies are broadly transferable to many local territorial governance practices in Latvia (Ernsteins et al., 2017a, 2017b, 2025; Konkovs et al., 2022; Ozolins et al., 2023).

These findings are broadly consistent with the international literature on municipal environmental governance, which emphasises that effective governance in SESs depends on integration, adaptability, collaboration, and learning rather than on regulation alone (Folke et al., 2005; Olsson et al., 2007). The results also support existing critiques of hierarchical command-and-control approaches, which often prove insufficient in territorially complex environmental contexts (Levin, 1999; Holling et al., 2002). In addition, the cases confirm earlier studies showing that the implementation of WFD principles often remains limited in practice, particularly in smaller water basins and rural territories where participation, coordination, and long-term institutional capacity are weaker or absent (Neto et al., 2018; Rimmert et al., 2020). At the same time, the national river basin governance system is still in the process of extending to small river basins through successive administrative levels, from the comparatively established national level to regional planning and further to the local municipal level (Ernsteins et al., 2025).

SWOT-based opportunities - threats: municipal and basin-based environmental governance

Across all three cases, Kekava Municipality, Lake Lubans and the Dviete River Basin, the identified opportunities are closely linked to sectoral diversification, external financing and stakeholder mobilisation. Nature-based and cultural tourism, together with broader eco-recreational activities, provides shared potential for simultaneously strengthening local economies and supporting conservation objectives. At the same time, EU and other international funding instruments, scientific cooperation, and new technological or digital solutions can reinforce evidence-based planning and help

operationalise system-based, cross-sectoral environmental governance at both municipal and river-basin scales.

The three cases also share several systemic threats that constrain effective environmental and water governance. Climate-change-related risks, including increasing eutrophication, extreme weather events and changing hydrological regimes, intensify pressures on ecosystems and local livelihoods. In addition, fragmented or rigid legal frameworks, insufficient and unstable funding for water management, overlapping institutional responsibilities and weak coordination across administrative levels limit the implementation of integrated, SES-oriented approaches. Social challenges such as depopulation, ageing and low environmental awareness further undermine stakeholder engagement and reduce the effectiveness of participatory governance instruments.

At the same time, case-specific opportunities and risks highlight clear differences between municipal and basin-type territories. In Kekava, urban proximity, stronger economic activity, regional cooperation, and participation in international networks create favourable conditions for integrating environmental objectives into development planning, but these advantages are offset by industrial pressures, rapid suburbanisation, and dependence on national financial equalisation. In contrast, the Lake Lubans and Dviete basin cases highlight opportunities related to unified basin management and tourism strategies, local consultative councils, and bottom-up conservation partnerships, yet they remain constrained by stricter nature-protection rules, invasive species and disease risks, unresolved land-use conflicts, and weak compensation mechanisms. These contrasts suggest that, although a common national framework and three-dimensional governance model apply, instrument design and participation must be territorially adapted by building on municipal economic and institutional capacities in Kekava and by prioritising conflict resolution, basin-level planning, and livelihood-based conservation in more peripheral lake and small-river territories.

Conclusions

The following conclusions are derived from a comparative assessment of three Latvian territorial environmental governance cases. Together, they reveal governance strengths, limitations, and development opportunities across different municipal and socio-ecological governance contexts.

Environmental governance: Kekava Municipality

1. The case of Kekava Municipality demonstrates that integrating environmental governance into the overall municipal management structure contributes to the effective incorporation of environmental considerations into development planning, property management, mobility, energy efficiency, and other municipal functions.

2. Kekava Municipality represents the most integrated governance case among the studied territories, combining diverse governance instruments, active stakeholder cooperation, environmental communication practices, and cross-sectoral environmental planning. However, its long-term effectiveness depends on strengthening the implementation of sustainability measures, particularly in renewable energy transition, sustainable mobility, waste reduction, broader stakeholder participation, and systematic monitoring and evaluation of environmental governance outcomes.

Environmental governance: Dviete River Basin

3. The Dviete River Basin demonstrates that the existence of formal environmental governance structures and instruments alone is insufficient to ensure effective governance, as fragmented institutional responsibilities, weak cross-sectoral coordination, and limited long-term administrative capacity continue to constrain environmental management and decision-making processes.

4. Although the Dviete River Basin possesses a strong environmental governance foundation based on valuable natural assets, planning frameworks, environmental monitoring practices, and active local initiatives, its future development depends on stronger stakeholder cooperation, participatory and bottom-up governance approaches, environmental communication, and the integration of environmental, water management, and socio-economic sectors through complementary governance instruments and collaborative governance arrangements.

Environmental governance: Lake Lubans

5. The case of Lake Lubans demonstrates that fragmented governance structures, insufficient stakeholder involvement, and the absence of a unified management framework significantly reduce the effectiveness of environmental governance and limit the integration of ecological, socio-economic, and tourism-related development objectives.

6. The long-term sustainable development of Lake Lubans requires the application of an SES approach that balances nature conservation objectives with local economic development, tourism, recreation, and community interests through integrated governance and planning mechanisms. This requires stronger stakeholder participation, environmental communication, collaborative governance structures, and monitoring-based adaptive management.

Comparative analysis and general conclusions

7. The application of the triple governance dimensions framework in three contrasting Latvian territorial cases demonstrates that governance effectiveness is determined by the degree of integration among governance sectors, stakeholder groups, and governance instruments. The findings show that governance performance depends less on individual governance arrangements than on their complementarity, interaction, and capacity to support adaptive and collaborative governance.

8. The comparative case-study analysis reveals a clear governance gradient between municipal and basin-based territories. The Kekava Municipality case demonstrates comparatively mature and integrated environmental governance, while the Dviete and Lake Lubans cases reveal lower levels of integration, coordination, and stakeholder involvement, particularly in SES-based governance.

9. Governance effectiveness depends not only on the existence of governance instruments but also on their complementary and coordinated application. Although planning, legal, financial, institutional, technological, and communication instruments are widely used, their implementation is often constrained by limited resources, short-term project dependence, regulatory complexity, and insufficient administrative capacity.

10. Stakeholder participation and environmental communication remain among the weakest components of local environmental governance. Communication, public involvement, environmental education, monitoring feedback, and collaborative decision-making are often fragmented or overly formalised, thereby limiting transparency, trust, social learning, adaptive management, and long-term stakeholder engagement.

11. The findings suggest that several governance limitations identified across the three cases - fragmented coordination, weak environmental communication, insufficient stakeholder participation, and limited implementation capacity - are not case-specific phenomena but are likely characteristic of a broader share of Latvian local environmental governance. This conclusion is consistent with previous Latvian and international environmental governance research.

12. Opportunities for strengthening environmental governance in Latvia include stronger municipal capacity, broader stakeholder cooperation among state institutions, municipalities, businesses, civil society, and mediating actors, greater involvement of NGOs, educators, the media, and scientific institutions, nature-based development, scientific cooperation, environmental communication, and EU funding mechanisms. However, these opportunities must be addressed alongside common challenges, such as climate change, demographic decline, infrastructure deterioration, institutional fragmentation, and increasing pressures on natural resources.

Acknowledgements

The authors acknowledge the contribution and con-financing of the Daugavpils University and University of Latvia, the Centre for Socio-Ecological Systems Governance, for support and main contribution in conducting these all-complementary studies, design and paper elaboration. The study was developed with support and within the frameworks of the two EU projects – EU Horizon project OPTAIN (Dviete river basin) and the EU LIFE project GoodWaterIP (Lubana lake basin).

GOVERNANCE FRAMEWORK FOR ENERGY-EFFICIENT HOUSING RENOVATION PROCESS: MULTI-APARTMENT BUILDING WITH COMPLEMENTARY ROOF-TOP SOLAR TECHNOLOGIES

***Raimonds Ernsteins, Ivars Kudrenickis, Liga Biezina, Rasa Ikstena**
University of Latvia, Latvia
*Corresponding author's email: raimonds.ernsteins@lu.lv

Abstract
The paper deals with the challenges of the complex renovation of multi-apartment buildings (MABs), joining within a single project both the 'traditional' increase in energy efficiency of MABs and the installation of on-site zero-emission technologies. Wide inclusion of rooftop solar technologies within the projects is still one of the weak points for necessary radical improvement of the renovation process of the MABs in Latvia. MABs could make an important contribution to this goal, and both solar thermal collectors (STCs) and solar PV panels must be adequately considered. However, up to now, rooftop solar energy in MABs in Latvia is a rare practice, meeting its penetration with both engineering and economic and social obstacles. Utilizing a case study research methodology approach centered on Valmiera municipality, the study employs a complementary mixed qualitative methodology comprising document and database studies, in-depth semi-structured stakeholder interviews, and observational studies. The results demonstrate that successful thermal renovation requires a dual approach: robust technical engineering must coexist with structured energy governance tripartite framework and process preconditions. Consequently, this underscores the significance of the standard governance process lifecycle, also post-implementation phases, and the application of an integrated triple-dimension-based governance framework that encompasses governance stakeholders, sectors, and instruments. Beyond these institutional frameworks, there are recognized crucial localised driving factors, including the accessibility of European Regional Development Fund (ERDF) and municipal co-funding, civic participation and household leadership, and a robust municipal intermediary management system, coordinated by the municipal management intermediary agency, serving as facilitating and renovation project manager.
Keywords: preconditions, governance framework, governance content, stakeholders, driving factors.

Introduction

The overall aim of the study is to structure and analyse success case of energy-efficient multi-apartment building (MAB) renovation with particular interest in rooftop solar technologies' application, recognising that successful thermal renovation requires not only robust technical engineering, but shall be complemented with structured energy governance process framing, and, subsequently, requesting to suggest and evaluate the potential governance framework and to recognise main preconditions and riving factors.

The European Union (EU) strives to be the first climate-neutral continent. The EU 'Climate Law' (European Parliament and Council, 2021) enshrines in the EU legal system the binding objective of climate neutrality at the latest by 2050, aiming to achieve negative greenhouse gas (GHG) emissions thereafter, first (December, 2019) stated by the European Green Deal (European Commission, 2019) in pursuit of the long-term temperature goal ('to limit the temperature increase to 1.5 °C above pre-industrial levels') set out in the Paris Agreement. The intermediate steps, relative to 1990, are a domestic reduction of net GHG emissions by 2030 by at least 55% (European Parliament and Council, 2021) and by 2040 by 90% (European Commission, 2025).

Renewable energy source (RES) deployment is one of the principal strategies to reduce GHG emissions. The revised in 2023 Renewable Energy Directive (European Parliament and Council, 2018) states the binding ensuring of the 42.5% share of energy from RES in the EU's gross final energy consumption (FEC) in 2030, endeavouring to increase it up to 45%. Mainstreaming of RES and increasing of renewable energy share should be provided in all energy end-use sectors. Particularly in the building sector FEC, the EU-wide indicative target is at least a 49% share of energy from RES in 2030.

Thermal renovations of MABs with roof-top solar technologies

In line with EU renewable energy policy and based on a high historical share (43.22% in 2023 (Official Statistics Portal of Latvia, 2023)), Latvia shall reach a 61% share of energy from RES in total gross FEC in 2030 (Republic of Latvia, 2024). Particularly in Latvia's building sector FEC, the share of energy from RES should increase up to 65% (indicative) from 60.6% in 2022. By installing on-site RES technologies, MABs could provide an important contribution for the further mainstreaming of RES in the building sector. For it, both rooftop solar photovoltaic (PV) panels and solar thermal collectors (STCs) and their combination with heat pumps (HPs) must be adequately considered. In the previous our study (Kudreņickis et al., 2024b), Latvia's potential for rooftop PV systems, to be installed by energy communities comprising MABs residents, has been evaluated at around 77 GWh electricity production in 2030 as the most substantiated scenario.

The revised in 2024 Directive on energy performance in buildings (European Parliament and Council, 2024) states the EU member states shall ensure the deployment of solar energy installations, if technically suitable and economically and functionally feasible, by 31.12.2029 on all new residential buildings. At the national level, the criteria for the practical implementation of this obligation shall be established,

and the supporting framework providing the necessary administrative, technical, and financial measures must be put in place. Although the directive does not contain the obligation to provide the deployment of solar energy in the MABs undergoing renovation, the research studies we refer to in the literature review section below confirm the solar energy technologies as one of the buildings' principal retrofit measures.

In the latest years Latvia has had a boom in the installation of solar PV microgeneration technologies in the residential sector – single-family buildings. However, the interest for SCTs is significantly lower.

By June 2025, the total PV systems generation capacity in Latvia has already reached 770 MW (around 30% of total RES facilities' capacity) (Sadales tīkls, 2025); five years ago, PV systems capacity was negligible (only around 3 MW). One can see the PV systems have become a highly important electricity generation source in Latvia. On the other hand, such development might also be evaluated as a disproportionately rapid increase in solar PV systems' capacity when many installers, particularly of large ground-mounted solar PV facilities, see the economic profit, not the ensuring of self-consumption.

The residential sector provides a highly important contribution to total solar PV capacity in Latvia. The total number of microgenerators (capacity up to 11.1 kW), connected to the power distribution grid at the end of June 2025, was 23,8 thousand, with the total capacity of 202 MW (Sadales tīkls, 2025). An important promoter of the PV system installation in single-family and detached houses is the national green investment scheme-emission allowances. Auctioning Instrument (EAAI, revenues of EU ETS emission allowances auctioning), established in 2022 and ongoing up to 2029 (inclusive), with the currently allocated aid volume of 85 MEUR, the programme supports the purchase of PV panel systems as well as electricity-storage equipment. At the end of 2024, within this programme, around 12,5 thousand PV microgeneration systems were installed with the total capacity slightly exceeding 100 MW. Techno-economic data are presented in Table 1.

In our case study region, Valmiera municipality, 380 PV panel systems (3% of Latvia's total) with a total capacity of around 3 MW have been installed (December 2024) (Latvian Environmental Investment Fund, n.d.). However, in the future, the installation path might decrease due to the change in the provisions for electricity exchange with the grid, namely, the net metering (in kWh) system for new entrants has been closed from the 01.05.2024, and currently the net payment system is available. We evaluate solar PV systems that are currently installed in around 4.2% of total single-family dwellings in Latvia, which is a good example of energy citizenship at the individual household level.

However, up to now, rooftop solar energy in MABs in Latvia is a (very) rare practice, meeting its penetration with engineering, economic and social obstacles.

At first, the PV technologies had not been included as the eligible ones within the MABs' renovation aid programme of the EU funds' 2014-2020 planning period; only RES technologies for heat production, such as STCs and HPs, were eligible. For the ongoing aid programmes, both financed by Latvia's Recovery and Resilience Facility Plan (RRFP) (Cabinet of Ministers, 2022) and Latvia's EU Cohesion Policy Programme for the 2021-2027 planning period (Cabinet of Ministers, 2024b), electricity microgeneration technologies are included as well as the eligible technologies to produce electricity for self-consumption (considered as the use of at least 80% of the electricity produced on an annual basis) to be consumed both in MAB's common areas and for serving engineering systems and equipment; however, this aid does not deal with the electricity sharing in MAB apartments.

Table 1

Average techno-economic data for the single project, supported by EAAI programme (Cabinet of Ministers, 2022)

	Capacity, per project	Financial volume, EUR		EAAI support volume	
		per project	per kW (kWh)	per project	per kW (kWh)
PV panels system	8.1 kW	6400	860	3260	400
Electricity storage system	12.2 kWh	4070	335	2427	200

Secondly, the adoption of energy communities' legislation in Latvia has been significantly delayed. Clear provisions for the operation of both jointly acting renewable energy customers and energy communities are the necessary precondition to unlock solar electricity generation at the MAB and neighbourhood levels. Although the general provisions related to active customers and energy communities have been adopted in July 2022 (The Parliament of the Republic of Latvia, 1998, 2005), the governmental regulation for registration and operation of energy communities has been adopted only recently, in December 2024, and only in May 2025 was it included in the regulation the detailed provisions on obligation electricity traders shall include the universal service of the energy community in their electricity trading offers (Cabinet of Ministers, 2024a). Also, the financial aid programme for energy communities in summer 2025 was still in interinstitutional harmonisation.

Thirdly, there are hindering governance obstacles. Installation of on-site zero-emission technologies in MABs in Latvia would contribute, through the

development of prosumerism, to the wider involvement of citizens in the energy system transformation processes. Studies on the success stories can provide valuable lessons for rooftop solar technologies' penetration.

The current study particularly focuses on the case of rooftop solar technologies in MAB in Valmiera City. In Latvia, we also are referring to the pilot practice of rooftop solar technologies in MABs in the Marupe municipality. An example of an STC (around 11 kW) installation in a historical building is a 7-apartment building (built 1898, comprises a private kindergarten on the ground floor) in Riga capital city. As in the earlier cases of STC installations in MABs in Latvia, it can be noted that a 30-apartment building in Sigulda town (combined installation in 2010 of 29 kW STCs and a 100-kW wood pellet boiler (Zandeckis et al., 2012) and an 11-apartment building in Rezekne (10 STCs). Worth noting also is the case of installing a ground-mounted larger-scale (259 kWp, 720 panels) solar PV facility, initiated by the village owner, to provide almost a fifth of electricity demand of Amatciems' green lifestyle community's detached single-family buildings (PV Magazine, 2022).

Integration of solar energy technologies along with the MAB retrofit

The application of solar energy technologies, as has been recognised from the literature review performed, is widely studied as one of the building retrofitting measures to upgrade it to a net zero energy building (ZEB). The recent review (Ibrahim & Harkouss, 2024), including more than fifty cases, presents that the installation of PV panels was done in all cases to achieve net ZEB. Regarding PV technologies, the 1st-generation silicon-based one still represents over 95% of the market due to its cost-effectiveness and maturity (International Energy Agency, 2022). Today PV panels are available in different types, expressions and colours, allowing them to be integrated aesthetically. At the same time, the rooftop or facade-sited PV panels are not the only solar technology; adequate attention has to be paid to the installation of STCs as well, particularly to the combined installation of PV panels and STCs. E.g., the recent (10.2024) review (Weerasinghe et al., 2024) has shown solar energy technologies are widely applied as one of the measures to retrofit existing buildings (considering all use-types) to net zero carbon ones and has identified 58 research papers analysing the installation of them, of which 17 papers relate to combined installation, 38 papers relate to only PV panels and 3 cases relate to only STCs; the reviewed papers had studied the performance of this retrofitting measure together with the economic feasibility and environmental impacts.

The studies, referred to below, characterise the research directions on rooftop solar technologies implementation along with building energy efficiency improvement; of course, the reference list provided is not exhaustive. Several studies have analysed solar technologies in single-family buildings, but we focus below on MABs.

The (Aljashaami et al., 2023) consider the solar heating installations currently available in the market as a successful alternative to traditional heating methods and evaluate their economic feasibility; the study is based on heating a house in Warsaw with the annual heat demand of 12.53 MWh. Two options have been considered: (1) using STCs in direct heat generation, while (2) using PV panels to generate electricity for DHW. The results indicated that STCs and PV panels contributed to the annual energy demand by 40% and 43%. Authors have found the annual costs saved when using STCs are 252 EUR if natural gas is the conventional energy used for heating.

Author of (Galvin, 2024a) underlines that rooftop PV has decreased sharply in price and continues to do so and, by exploring the economics of installing PV systems along with building energy-efficient renovation based on the case study of two typical apartment buildings in North Rhine-Westphalia, applying net-present value cost-benefit analysis, demonstrates that rooftop PV systems can provide significant gains, particularly in combination with HPs. The author emphasises that the costs of energy efficiency renovation of Germany's postwar apartment buildings have sharply increased since pre-Covid years and thus considers rooftop PV systems as the important measure to increase the economic viability of MABs retrofit. Improvement of retrofit economic viability by solar technologies is a particularly important solution due to several studies: (Kazukauskas & Li, 2024) (Lithuania case); (Galvin, 2024b) (Germany case) and (Hirvonen et al., 2022) (Finish case) have concluded that in case of enough deep renovation, the costs of renovation might not be offset by energy cost savings. Also, in our previous paper (Kudreņickis et al., 2024a), there were identified MABs with high specific renovation costs within Latvia's related 2016-2023 national programme, being co-financed by the European Regional Development Fund (ERDF).

The (Galvin, 2024a) also clearly shows the opposite link, namely, not only does PV improve the economic viability of MAB retrofit, but also MAB retrofit improves economic viability of rooftop PV systems. Without such a combination with the retrofit, installing PV systems makes it useful only for the normal electricity load, while the rest of the electricity production must be fed into the grid for the small gain. Thus (Galvin, 2024a) emphasises both policymakers and property owners should consider the economic usefulness of rooftop PV systems not only for new buildings but also as an important supplement to energy-efficient renovation and recommends the promotion of the shared rooftop PV systems as the norm within comprehensive energy-efficient renovation of MABs.

Well-governed subsidy schemes must be understood as the important tool to promote solar technologies, and high attention must be paid to improve existing

aid, both at national and municipal levels. On the other hand, Galvin (2022) calls for a careful assessment of PV systems' size, namely, the approach of installing PV panels to generate as much energy as the building uses over the year (if roof area is available) may lead to the installation of a significantly larger PV system than is technically optimal, and it would be more economical to invest in remote wind power (e.g., the energy community approach) than in excess PV capacity. Importantly, optimising the size of the HP and incorporating thermal storage can provide good systems performance and efficient use of PV panel-produced electricity even in colder climates (Mussard, 2017), such as Germany.

Regarding the expected future cost reduction of residential rooftop PV panels systems, the Danish Energy Agency (n.d.) provides for a 32% cost reduction in 2030, a 44% cost reduction in 2040 and a 48% cost reduction in 2050, compared to the 2020 cost; it is also expected the decrease in the specific space requirement per installed kW will be around 10% in 2030, 16% in 2040 and 21% in 2050, compared to 2020, as well as the technical lifetime will increase by 5 years in 2040.

The study (Hajian, 2024) analyses the renovation measures implemented under the ARA renovation subsidy program in MABs in Finland - the most typical renovated building from the 1970s. Authors conclude, ʻExhaust air HP, window replacement and PV were the most cost-effective options, while packages with additional insulation faced considerably higher costs. Both STCs and PV panels are included in the optimal energy retrofit scenario of the Finish building stock by 2050 (Hirvonen, 2021). In its turn, Rehman et al. (2022) design and model a renewable-based energy system for a real demo apartment building in Finland to be a positive energy one; the simulation of the integration within the building of such technologies as a PV-thermal system, HP, seasonal thermal storage, and wind turbines is provided.

The authors conclude that in the Nordic conditions, it is difficult to reach the positive energy building level in urban areas if all the building's energy demands (heating, cooling and plug loads) are included, and for it, both on-site and off-site (the building boundary is extended to a virtual boundary outside its physical boundary that allows the addition of more renewable generations) technologies will be needed as well as, if applicable, changing the building's shape that allows more installations on the roof.

Authors evaluate, compared to the building cost, the energy system cost is generally low, i.e., around 1.2–4.3% of the building cost. Similarly, PV modules on all buildings with available roof for it (assumed to be installed on 30% of all available roof space) and switches to HPs of different types (ground source, air source, and hybrid ones) are included in the net zero by 2050 retrofit scenario for the English housing stock (Li, 2022).

It is important to evaluate the integration of rooftop solar technologies within the renovation of Soviet-type MABs; for this, we refer to cases in the Baltic States.

The 5-storey concrete prefabricated panel MAB (built in 1986, 80 apartments) has been renovated in 2017 to realise the near-ZEB renovation pilot. District heating (DH) remains as a heat source. It has been installed: (i) PV panels (55 ones, total peak power of 14 kW); (ii) half of the building has an additional heat source from STCs (50 STCs with a total effective area of 100 m², four 1.5 t storage tanks); and (iii) half of the building has an additional heat source to pre-heat the incoming cold water before the heating sub-station from a passive wastewater (grey water from showers and sinks) heat recovery system (Hamburg, 2020). Ex-ante total renovation costs (excluding costs of the modernisation of apartments), taken from the estimations of the construction companies, were around 860 thousand EUR, of which PV panel costs are around 6% and STC costs around 10.4% (Kuusk & Kalamees, 2015). After renovation: heat energy need – 51 kWh m^{-2} per year, of this STCs provide 7 kWh m^{-2} per year and wastewater heat recovery 15 kWh m^{-2} per year; electricity need – 36 kWh m^{-2} per year, of this PV panels provide 2 kWh m^{-2} per year.

The study (Valančius & Mikucioniene, 2020) analyses in-depth the technical options to install rooftop solar technologies during the renovation of Soviet-type MABs in Lithuania; the buildings are connected to the DH system. Applying a computer simulation tool, the authors conclude that to optimally generate energy in these buildings, the following areas of solar technologies are efficient: 120 m² of flat-plate STCs, balanced along with two 3 m³ storage tanks, and 205 m² (30.6 kW) of PV panels for a 5-storey building (roof area 723 m²); (ii) 70 m² of STCs, balanced along with two 2 m³ storage tanks, and 105 m² (17 kW) of PV panels for a 9-storey building (roof area 545 m²); and (iii) 60 m² of STCs, balanced along with two 2 m³ storage tanks, and 100 m² (16 kW) of PV panels for a 16-storey building (roof area 542 m²). Authors underline ʻFrom an architectural point of view, the roof of a 9-storey multi-apartment building is inconvenient when modelling solar technologies due to large constructional areas for lifts which causes shading'. The completed model shows that one kW of installed PV panels produces 944.85 kWh (5-storey building), 892.8 kWh (9-storey building) and 848.73 kWh (16-storey building) of electricity annually, e.g., there is about 10.7% constituting losses from shading as from structures on the roof of the 16-storey building.

Table 2 presents the simulated solar energy production. Part of the demand for domestic hot water (DHW) preparation in a 16-storey building is covered by HP as well. Considering only the electricity demand of common areas (stairwell lighting and lifts, the latest for 9- and 16-storey buildings), 100% of the demand would be met in the case of 5-storey and 9-storey buildings and around 50% of the demand for 16-storey buildings.

The study by Borodinecs et al. (2024) analyses actual (hourly real) electricity consumption data from 31

dwellings in a typical 5-storey 60-apartment building in Riga. Authors provide the detailed analysis of both household electricity consumption data and household characterising parameters (household size, population, etc.) to predict household load and ensure the optimal design of a MAB-scale PV system. Findings indicate a rooftop PV system on such a building can cover up to 77% of annual electricity consumption (the difference with the results of the Lithuanian study might be explained by the fact that in the previous reference the part of the roof was used for the installation of STCs); the results of the study also provide valuable information for the optimisation of on-site energy storage.

Table 2

Solar energy production in soviet-type multi-apartment buildings: single table for simulation data as from (adapted from Valančius & Mikucioniene, 2020)

Building	Number of occupants	Annual heat production by STCs	Share of DHW preparation, covered by STCs	Annual electricity produced by PV panels	Share of electricity demand, covered by PV panels	Annual electricity still to be supplied by the grid
		MWh	%	MWh	%	MWh
5-storey	140	62.8	60.9	29.980	44.7	37.07
9-storey	160	43.9	43	15.714	15.6	84.93
16-storey	184	37.7	33.7	13.537	9	149.56

The study in Latvia comprises two apartment buildings in the Marupe municipality: (1) a 3-storey MAB counts 4 PV panels (1.32 kWp) and 18 STCs (27 kW, expected annual heat production of 20 MWh). The produced electricity is used to cover electricity consumption in the common areas of the MAB; the produced heat is used for pre-heating of DHW for the needs of all residents (the building is connected to the DH system). (2) The row-house building counts 6 rooftop PV systems, each with 4 PV panels with an individual capacity of 330 W; each PV panel system has its own inverter connected to the inner power grid of the particular section of the building. Thus, the total PV system comprises 24 PV panels with a total capacity of 7.92 kWp. In annual terms, it covers around 30% of annual consumption, and there is net zero electricity supply from the grid in summer months. The produced electricity is used also for the charging of electric vehicles owned by residents of the row houses.

Energy Governance: theoretical approaches and best practices in residential renovation

The European Court of Auditors (ECA, 2026) summarized the core strategic mandates of the European Union, noting that renewable energy developments are vital to achieving the EU's long-term objective of climate neutrality by 2050. To this end, the EU established a target to increase the renewable energy share from 25.4% in 2024 to 42.5% by 2030, projecting that half of all EU citizens could generate approximately 50% of the bloc's renewable energy by 2050. Crucially, the 2022 EU Solar Energy Strategy introduced a political objective binding the EU and its Member States to establish at least one renewables-based energy community in every municipality with a population exceeding 10,000 by 2025 (European Court of Auditors, 2026). Directive (EU) 2018/2001 on the promotion of the use of energy from renewable sources (RED II) legally defines these energy communities as 'legal entities that empower citizens, small businesses and local authorities to produce, manage, share and consume their own energy'. However, the European Court of Auditors' Special Report 10/2026, titled *'Energy communities – Potential yet to be fulfilled',* concluded that the EU failed to meet this target. By January 2025, only 27% of the objective had been realized, primarily because national governments failed to establish the regulatory and administrative conditions necessary to support community development (European Court of Auditors, 2026). Complementing these findings, an Interreg Europe (2026) policy brief emphasized that energy efficiency management barriers in multi-apartment building renovations—such as fragmented ownership and disparate financial capacities—necessitate tailored local governance, targeted technical assistance, and dedicated funding models to overcome the logistical and social hurdles inherent in collective action.

Energy governance is increasingly understood as a multi-level, multi-actor process rather than a purely technical management challenge. Contemporary research emphasizes that achieving climate neutrality requires coordinated action among governments, municipalities, private organizations, financial institutions, and citizens (Björklund et al., 2023). Consequently, energy governance has shifted **from traditional regulatory frameworks toward collaborative models** that integrate policy coordination, stakeholder participation, and institutional capacity across all levels of government. These approaches recognize that successful energy transitions depend on the strategic interplay of regulatory, economic, technological, and social

instruments, rather than on isolated policy measures (Björklund et al., 2023).

The literature highlights that building renovation should be analyzed as **a socio-technical system**, wherein technical solutions interact dynamically with institutional arrangements, financial mechanisms, behavioral factors, and governance structures (McCarthy et al., 2018). Systems thinking, multi-level governance theory, and collaborative governance represent the dominant theoretical perspectives explaining how diverse actors collectively influence energy transition outcomes. These frameworks demonstrate that fragmented responsibilities and weak institutional coordination remain primary barriers to achieving large-scale energy efficiency improvements in the residential building sector (McCarthy et al., 2018; Björklund et al., 2023).

A particularly critical governance perspective concerns multi-owner residential buildings, where renovation initiatives require collective agreement among apartment co-owners. Ownership structures, voting rules, legal responsibilities, and organizational frameworks heavily influence whether energy renovation projects are initiated and successfully executed (Bright & Weatherall, 2017). Research consistently concludes that **institutional and governance arrangements often constitute greater barriers** to progress than technical limitations, particularly within European condominium and apartment buildings (Bright & Weatherall, 2017; McCarthy et al., 2018).

International evidence indicates that the most successful building renovation programs pair regulatory mandates with financial incentives, technical assistance, and robust stakeholder engagement. Rather than relying on a single policy instrument, best practices integrate legislation, subsidies, advisory services, one-stop-shop support structures, digital tools, and long-term governance coordination. Such integrated frameworks substantially increase renovation rates while simultaneously optimizing energy efficiency and fostering public acceptance of renovation initiatives (Björklund et al., 2023).

For multi-family residential buildings, established best practices place additional emphasis on participatory governance and collective decision-making. Studies demonstrate that successful renovation outcomes rely on transparent communication, mutual trust among residents, effective property management, clear institutional mandates, and accessible financial mechanisms. Early stakeholder involvement and coordinated governance mitigate conflicts among apartment owners and significantly improve the implementation rate of deep energy renovation projects. Ultimately, this **positions governance quality as a decisive factor alongside technical and financial variables** (Bright & Weatherall, 2017; McCarthy et al., 2018).

The Triple Governance Dimensions Framework model application

The environmental governance process—spanning sectors such as energy, climate, water and other—is rooted in the effective realization of a cyclical societal decision-making process that encompasses decision preparation, making, execution, implementation, and monitoring. The success of this cycle depends heavily on institutions, formal and informal structures, stakeholder engagement, and collaborative interactions aimed at problem-solving within a particular environmental domain or sector. Drawing from environmental science and management research, as well as development project practices, ther was proposed (Ernsteins et al., 2017, 2024) the generic **Triple Governance Dimensions (TGD) framework.** This model integrates three complementary pillars: governance stakeholders (who), governance content (where/what), and governance instruments (how). Together, these components provide a comprehensive framework for both **analytically examining and structurally framing governance processes.** The TGD framework is grounded in core governance principles operating within a complex, multi-sector social-ecological system (SES), interlinking a multi-actor stakeholder system with an adequate, complementary multi-instrumental system.

The governance content (sectors) dimension covers all thematic areas addressed by environmental governance. Beyond traditional environmental protection and infrastructure sectors - such as biodiversity, water, energy, waste and others - this dimension increasingly incorporates socio-economic sectors to reflect a holistic social-ecological systems approach. This includes fields such as health, education, agriculture, forestry, tourism, and culture, thereby aligning governance with an integrated sustainable development perspective (Ernsteins et al., 2017).

The governance stakeholders (segments) dimension encompasses the entire system of principal actor groupings involved in or influencing the governance process. Five distinct stakeholder segments are identified: the state/national level, municipalities, businesses, society/households, and mediators. The mediator segment - comprising media, formal-nonformal educators, NGOs, and academia - plays a vital role in facilitating communication, knowledge exchange and collaboration across governance segments, sectors, and levels (Ernsteins et al., 2017).

The governance instruments dimension refers to the mechanisms deployed to implement the governance process. These instruments encompass policy and legislation, planning, institutional and administrative measures, economic and financial tools, infrastructure and technology, and communication and collaboration. Together, this is a complementary system for effectively addressing complex governance challenges (Ernsteins et al., 2017).

Presumably, the technical and engineering excellence,

alone cannot solve the residential energy efficiency gap. Successful **thermal renovation requires a dual approach** – also the governance process and structured governance framework are to be studied and potentially elaborated for further application in municipalities to translate climate policies into community-led, solar-integrated building transitions.

Research Aim for this Valmiera municipality energy renovation case study is to analyze how energy governance framework and process cycle and localized driving factors influence the successful implementation of energy-efficient renovations and rooftop solar integration in multi-apartment buildings.

Research Tasks: 1. To conceptualize and apply as analitical frame a three-dimensional energy governance framework complementing stakeholders, institutional sectors, and governance instruments; **2.** To evaluate the entire governance lifecycle, including implementation and post-implementation phases, of building retrofits in Latvia; **3.** To investigate the localized drivers and intermediary structuring in Valmiera municipality case study.

Materials and Methods

The current study particularly focuses on the MAB renovation case with rooftop solar technologies in the Valmiera City municipality, which is one of the most pro-environmental and pro-energy active municipalities in Latvia. The **case study research methodology** has been applied, using complementary research methods: document and database studies, deep semi-structured interviews, and visual observation, thus allowing application of analytical frame of chosen the **tripartite complementary governance dimensions framework** - involvement of relevant stakeholders, understanding related governance sectors, and, finally, all the governance instrument groups that are to be applied.

The energy-efficient renovation of the multi-apartment buildings was analysed in the context of the energy citizenship (ENCI) concept as a part of the EU Horizon project (2021–2024) EnergyProspects (EnergyProspects Project, 2024). As outlined in this EU project, the methodology for gathering comprehensive cases has been formulated to encompass and amalgamate various research interests and methodological needs.

The **case study-based research and development framework** was applied for the chosen non-traditional MAB's energy-efficient renovation case, possessing also in Latvia still quite rare renovation projects with the distinction of the complementary application of rooftop-based solar technologies. MAB is in Latvia's north-eastern Vidzeme region in Valmiera city centre on Riga Street 18 (MAB-RS18). Valmiera county municipality (Valmiera city and rural municipal administrative territories), having developed and introduced several energy governance initiatives and governance, also practical management, instruments.

During energy-efficient MAB renovation case studies, complementary (also eventually integrated) research approaches and methods were used, combining engineering-building work studies and sociological-governance process studies, realised by a set of sociological research methods.

Engineering framing and building process studies context

The overall summary of the MAB energy-efficient renovation work developments and situation in Latvia in general and for the whole territory of Valmiera city municipality and all Valmiera district (rural) municipalities (separate municipalities before the national administrative-territorial reform of 2021) has been realised already during the first phase of the case study research of the EU Horizon project EnergyProspects, which has been already presented in our previous paper (Kudreņickis et al., 2024a).

Besides various results recognised at the first phase of the research, there are to be mentioned that though ~ 60% of building renovation cases are carried out by the MABs which have established a legal management form – a housing association – the municipal housing companies still have a role, if such a municipal company has proven its operational reliability. Also, it was recognised that the installation of renewable energy technologies as an integral part of MAB's complex renovation was a very rare practice. Taking both mentioned aspects into account, it was decided for further studies (second phase) to focus on a realised practice example where rooftop-based solar technologies have been successfully carried out and the coordination role of municipal housing enterprise was comparatively crucial.

During the second phase, currently described for this paper, there was an initial evaluation of the results of the multi-apartment building renovation programme in 2016-2023 – the database (EXCEL sheet) of the national level MAB programme administrating institution ALTUM (JSC Development Finance Institution ALTUM) (ALTUM, 2025). The database has detailed information for all and each project in Latvia, both completed and ongoing. The summarised information from the database was prepared and could be seen as additional value of the presented study. The analysed MAB-RS18 case renovation example was submitted for the national competition 'Most Energy-Efficient Building in Latvia 2020' and received:

- The innovation award by the MABs' national-level renovation programme administrator ALTUM,
- A Certificate of Appreciation from the competition organisers for installing STCs during the renovation.

The governance process of socio-ecological system changes studies context

Further on, there were studies done of the MAB renovation building works processes in the Valmiera municipality and, especially, its municipal enterprise 'Valmiera Housekeeper' Ltd (PSIA *'Valmieras namsaimnieks'* in Latvian), working with contracted

MAB's everyday management and exactly with renovation projects if assigned and, subsequently, cooperating with MAB apartment owners and owners' associations.

The case study research complementarily included the following set of methods:

- all related document studies (national and municipal legal, planning, administrative, etc., documents, including also project-based documentation).
- Already mentioned and various other available regional and local database analyses.
- Six deep semi-structured interviews with the main MAB renovation case content-based stakeholders at the municipal level – 3 specialists from various related municipal administration levels and departments, 2 related specialists (including MAB-RS18 project manager) from municipal enterprise 'Valmiera Housekeeper', as well as MAB-RS18 flat-owners council chairman (house elder, also initiator of the project). The results of the interviews were complementary to those of document studies and the database analysis.

Besides MAB-RS18 flat-owners and their council, the project case key management stakeholder was Valmiera municipal enterprise 'Valmiera Housekeeper', as all the MAB-RS18 case project process cycle was planned and realised by this municipal enterprise – starting from the preparatory stage; design and development stage, including all stakeholders' and contractors' (building company and loan-issuing bank) involvement; and, further on, also coordination work during the implementation management stage.

In 2001 the municipality of Valmiera city decided to establish a limited liability company to be 100% owned by the municipality itself, and, besides several minor private housekeeping companies in the market, it is now the leading MAB management company in Valmiera. The company now manages 94 multi-apartment residential buildings; 4 multi-apartment residential buildings belonging to the municipality, as those cannot be transferred for privatisation; and, finally, also 14 multi-apartment residential buildings where apartment owners still have not chosen a housing management company. Until now, the company has managed complex renovation work in the 54 multi-apartment buildings of the city, but 5 buildings are partially renovated.

Direct information as well as the combination of information allowed the study of the following key research questions (in general, prescribed for all case studies of all partner countries of the EnergyProspects Project (EnergyProspects Project, 2021–2024) related to energy-efficient renovation of MABs and the perspective of STCs, e.g., rooftop solar panel project extensions – questions on basic **conditioning and driving factors and intermediation**.

The central research question: Why and under which conditions do energy-efficient MAB renovation cases achieve their goal(s) and make achievements towards the democratisation of the energy system? Relatedly, the prescribed interview questionnaire for all the case studies was elaborated in the EnergyProspects Project, having additional expansion on triple dimensions governance framework and Latvia case specifics.

Results and Discussion

Case study research was performed for the one MAB renovation case, but non-traditionally in Latvia, also complementary doing it with the installation of solar thermal panels – the MAB-RS18 case – focusing on renovation works and, especially, on governance processes and frames.

1. MAB renovation: engineering framing and building process context

The silicate brick 3-storey (with underground storey) MAB located in the Valmiera township municipality centre (120 km north-east from the capital city Riga) on Riga Street 18 (MAB-RS18) was built in 1960 and comprises 16 apartments with a total area of 1374 m² and 3 commercial areas.

An energy audit and efficiency assessments of MAB were done in 2013, and its report and forecasts are available, providing information about the building's energy efficiency for the further project design.

The components of preparing the renovation project application shall include the calculated energy efficiency assessment of the building, which covers the following main energy consumption areas, such as heating and DHW preparation. Regarding heating, evaluation includes the building's heating system, an analysis of heat loss, and potential improvements to reduce energy consumption during the colder months. For DHW preparation, the efficiency of DHW production systems is evaluated, and elaborated proposals for improvements, including the installation of STCs, are made.

These areas are thoroughly analysed to provide accurate forecasts of possible improvements that could reduce overall energy consumption and ensure more sustainable building operations. Additionally, various assessments and forecasts of energy efficiency improvements are made, considering the latest technologies and solutions. Furthermore, a certified construction evaluation is included, which is a crucial part to ensure that the proposed changes comply with all technical requirements and regulations. This evaluation provides a well-founded analysis of the planned actions, ensuring that the building meets energy efficiency standards and will be economically viable in the long term.

The energy audit also includes the cooling system (evaluation of climate control systems, determining energy consumption during the cooling season and possible improvements) and the mechanical ventilation system (the efficiency of the building's ventilation system, evaluating energy consumption and opportunities to improve air quality while reducing energy loss); however, for the particular building in these categories, there is no energy consumption.

However, an appropriately assessed and designed renovation project proposal has been dormant for several years, as the MAB-RS18 house case, due to its specific legal and administrative status conditions, was not directly corresponding to EU co-financing requirements, being established by the Cabinet of Ministers in Latvia.

2. MAB renovation: solar thermal panels

The MAB, located at Riga Street 18 in Valmiera city in 2018, has realised a successful self-initiated project for building renovation and improving its energy efficiency, combining it with **the simultaneous installation of rooftop STCs**. The initiative was led by the building residents' council chairman (house elder) and approved by the apartment owners. Thus, this is a sustainable and environmentally friendly pioneering example of combining such a complex house upgrade with MAB-scale energy self-production.

Before the renovation of the MAB, the energy efficiency performance for heating was higher than the maximum threshold of an 'E' class building (125 kWh m^{-2}), as stated by Latvia's national legislation (Cabinet of Ministers, 2021). As the result of the project, high specific heat energy saving is reached, contributing to climate change mitigation by saving 22.85 CO_2 eq. tonnes (SIA Valmieras Namsaimnieks, n.d.). According to the provisional energy performance certificate, the building's energy efficiency rating is 89.09 kWh/m^2 per year. In its turn, 2024 consumption data indicate total heat consumption, supplied from the DH system, is around 74 kWh m^{-2}, of which 67 kWh m^{-2} is for heating and only 7 kWh m^{-2} is for hot water preparation. Thus, the building now is close to the 'B' class (maximum threshold for thermal energy consumption for heating is 60 kWh m^{-2}). More details regarding building energy performance are presented in Table 3 below.

Older apartment buildings not yet renovated require not only facade insulation but also internal system upgrades using various infrastructure and engineering solutions. Thus, the renovation was complex, including house wall, basement, and attic insulation; foundation's hydro-insulation; window, door, and roof replacement; water and heating system reconstruction; ventilation system improvements; electrical system upgrades; and lightning protection installation. An important factor is the implementation of an internal heat supply system with an independent connection to each apartment and hydraulic balancing valves - this activity was also part of the building upgrade project. The summary on technical details of upgrade activities is provided in (National Competition 'Energoefektīvākā ēka Latvijā', n.d.).

Table 3

Riga Street 18 Building energy performance

Indicators/indices	Units of measurement	ALTUM before renovation	Target indices by energy certificate
1.Energy efficiency performance	kWh m^{-2} per year	200.7	137.6
1.1 for heating	kWh m^{-2} per year	139.5	79.3
1.2 for hot water preparation	kWh m^{-2} per year	61.2	58.3
2. Heat loss factor of the buildings enclosing structures (H_t)	W K^{-1}	1798	737
3. Heat loss factor of the building ventilation (H_{ve})	W K^{-1}	460	418
4.Air exchange rate	1 h^{-1}	0.55	0.5
5. Internal heat gains	kWh m^{-2} per heating period	38.9	38.9
6.Solar heat gains	kWh m^{-2} per heating period	16.6	12.8

Thus, inclusion in the project of the rooftop STCs was bringing a rather small addition to the project's total costs. Although installing rooftop solar energy facilities requires additional investment, it provides long-term financial savings for residents.

Nevertheless, during the EU funding period of 2013-2020, Riga Street 18 building is one of only two MABs in Latvia where residents have used ERDF co-financed MABs' energy efficiency improvement programme.

The project's total financial volume is 266,856 thousand EUR, of which ERDF co-financing had been planned for 50% (133,428 thousand EUR). The decision on granting ERDF co-financing was done on 23.05.2018. The upgrade works were performed from 05.07. to 14.12.2018. After completion of the project, ALTUM evaluated the eligibility of costs and, on 18.04.2019, approved the grant of 132,572 thousand EUR (ALTUM, 2025). Thus, the project had been well implemented along with the planned course. The co-financing was also provided by the Valmiera municipality budget sources (co-funding is available up to 20,000 EUR for renovation and other works in MABs' housing and courtyards upgrade).

The total capacity of installed rooftop solar thermal collectors is 14.74 kW. The solar system operates for 6-7 months per year (April–October), covering 60-70% of the annual energy demand for water heating. However, there was also the indicated imperfection in the initial project – namely, the building's roof load capacity was not properly assessed in the project; as a result, cracks have formed in the roof due to the excessive load from the installed solar thermal collectors.

Most renovation building tenders for MAB are won by

building companies which develop standard renovation projects sometimes without conducting on-site inspections. To mitigate this, the 'Valmiera Housekeeper' has introduced a new practice: hiring an additional engineer to verify project accuracy and correct errors before final approval.

3. MAB renovation: governance process and framework requirement

All inhabitants took part in the preparation process and making a joint decision (majority decision-making) to collaborate jointly to prepare a project proposal for energy renovation of their house and using solar panels for water heating – this was done in 2013, but the building project was accepted by the municipal building department in 2014. Then they were contacting their house management organisation – the municipal enterprise 'Valmiera Housekeeper' – to proceed with all necessary steps to get co-funding from both the Valmiera municipality (up to 20,000 EUR, bylaw of the municipality) and the national housing energy renovation support/co-funding financial institution Altum (with ERDF funding).

Due to the legal status, etc., specifics of their building and some limitations by national legal documents (related regulations of the Cabinet of Ministers of the Republic of Latvia), this was initially not possible; even the community of apartment owners of this house have managed to stepwise gather their own co-funding for any works on/with their building. After certain changes of the mentioned regulations in 2017, there finally appeared a possibility to re-activate their project proposal, and after a whole range of preparation procedures, organised by their communal services provider municipal enterprise 'Valmiera Housekeeper', the renovation works started in 2018.

The legal status of all inhabitants of this building is the community of apartment owners, and there is special national law for this. The general community of apartment owners of this apartment building have not decided to establish a particular association of apartment owners as a next and legal status, but instead they have agreed (long ago) to be participants of the municipal enterprise 'Valmiera Housekeeper', which has agreements with about 1/2 of multi-apartment buildings in Valmiera town to organise energy supply and other household services.

As said in the interview – the main reason to establish an association of apartment owners is the non-satisfactory work (also attitude and communication with inhabitants) of the mentioned municipal enterprise, which was not the case for this situation, even though there are issues which apartment owners would like to be solved better, incl. having more communication and housing parameters monitoring.

This collective case relates to direct energy consumption (energy saving) and decentralised energy production building projects. The case has been implemented in an urban area. **The three aims were**:

1. get energy savings and thus get economic benefits,
2. increase heat energy self-production and greater local community ownership of a decentralised energy system as the energy use and local independence in the preparation of hot water for inhabitants.
3. increase of inhabitant's self-awareness and being proud to be part of a sustainably thinking community.

Initially there was some scepticism on the necessity of solar panels since limited info was available around; also, municipal service provider companies have had no experience with solar panels as well as not clear info/background to get co-funding.

The general situation with the dwelling was comparatively negative (energy supply system, visual aspects of the dwelling, house yard qualities, etc.), but there were no real initiatives and active participation to start to work with these housing problems – in this situation, initiative was taken by the house council chairperson (contact person of this questionnaire – having an engineering education and working for Valmiera municipal water company). Coming with his ideas/proposals and being supported by some other persons from the council. Stepwise, most of the inhabitants were informed and negotiated, and finally, the majority agreed – all inhabitants are satisfied with the project results.

The decisions by the community of apartment owners of the building were done by consensual decision as majority decision-making.

The first initiative was taken by two individual persons, being members of the House Council (to be elected) and expressing their view on the bad situation with the inner and outer status of the common dwelling. This was followed by individual discussions, particularly done by MAB older members (members of the House Council) of each staircase of the dwelling with their flat owners. Finally, at the joint meeting (there were first several meetings) of the community of apartment owners, it was decided to go for the project – the majority were supporting this decision, a few persons had no pros/cons, and a few were worried about long-term investments.

Two persons from the House Council, understanding the potential of sun panels to reduce inhabitants' expenses and being environmentally friendly, and knowing that exactly one side of the roof is located towards the south, came with a proposal to include solar panels in the project.

3.1. Governance framework instruments dimension

In the MAB renovation process, there could be recognised all the six various groups of instruments being needed so that the case can achieve its goals:

*a) **Institutional and administration instruments***

Structuration and organisation of the functioning of the case: entities composing the case, legal status, coordination of the various activities (capacity building – energy production retail, etc.), negotiating with administrative authorities, etc. – The main/key player for this case – Municipal company 'Valmiera Housekeeper' – all initial audits and project works,

also financial management and building works, were done via this company in principal partnership with RS-18 house flat owners.

Including also - ***Networking and coordination intermediation*** with actors that present similarities with the case, enabling cooperation between actors, building and managing networks of multiple stakeholders, and exchange of knowledge and visions – for knowledge/expertise exchange again, company 'Valmiera Housekeeper'

b) ***Financial and economic instruments***

Capitalisation and resource mobilisation are required for the case to build up and sustain/grow – crediting bank, company 'Valmiera Housekeeper', co-funding by municipality and national agency Altum.

c) ***Communication complementary instruments***

Communication activities making the case public: consult demand-side for implementation, mediation activities, and put suppliers in contact with end users – very limited, as this case was quite closed as just a particular building activity (municipal public relations department and company 'Valmiera Housekeeper').

Including also - ***Technical and scientific intermediation***. Technical and scientific expertise activities for concretising the project: ICT conception, planners, architects, PV or wind power specialists, monitoring of the project, facilitating experimentation and pilots, facilitating/supporting adoption and implementation of innovations, etc. - as a technically based project – auditors, architects/planners, solar panel experts.

d) ***Policy and legal-regulatory instruments***

There was legal/regulatory intermediation in terms of project proposal dependency on governmental legal acts and regulations, particularly on co-funding possibilities. So, also, the national cabinet of ministers is to be mentioned here.

e) ***Planning instruments***

Here is to be mentioned both: mandatory/statutory planning documents (not only at the national but also, importantly, at the local level); voluntary thematic documents such as municipal climate, energy planning, etc., being interlinked with related financial and admin structures, etc.

f) ***Infrastructure and technology instruments***

Also, the key instruments group being studied in detail to some extent by all stakeholder groups and being enough carefully monitored during the project management process and afterwords.

3.2. Governance framework sectors and stakeholder's dimensions

The sector dimension distinguishes four closely connected fields, also being parts of building renovation project and process: environmental-energy, socio-economic, technological-housing and administrative-institutional. While Latvia has achieved substantial milestones regarding legal frameworks and technological integration, progress surrounding economic affordability and institutional implementation capacity remains fragmented. Households navigate these structural dimensions simultaneously. Subsequently, the role of stakeholders, especially, intermediaries are high.

There are to be recognised several groups of stakeholders, that were part of this renovation project, and actually the full set of all 5 stakeholder's (actors) groupings.

a) ***Governmental actors*** (i.e., intermediaries created by government): agencies that manage programmes with loans and technical assistance); governmental agency ALTUM was commissioned for managing programmes with loans (EU EBRD).

b) ***Municipal actors.*** *V*arious involved municipal departments and institutions, and, especially, the main/key player for this case again shall be mentioned also – the municipal company 'Valmiera Housekeeper' – all initial audits, project works, financial management, and building works were done via this company. Also, the municipal building department – to approve building projects.

c) ***Community/households actors.*** Individual flat owners of the MAB in Rigas street 18 and their representation being in regular communication process with all stakeholders around.

d) ***Business actors.*** For knowledge-intensive business services (banks who offer loans, mortgages, consultants, business lawyers, etc.) - bank for getting a loan and building company, as well as various materials and constructions suppliers.

e) ***Mediators segment actors:***

- ***Media and other information*** stakeholders – limited involvement for current project, but important for long time period renovation process.
- ***Education actors - intermediaries*** (independent research and education organisations/networks) – very limited engagement for this project, but with certain function in long-time municipal efforts for renovation.
- ***Non-government actors - intermediaries.*** Sector organisations (civil society umbrella organisations, transition towns) – non-existent here for this sector. Locally there are no environmental/energy NGOs, nor national energy NGO associations.
- ***Academia-knowledge institutions*** – very limited involvement for current project, but growing role ahead as having university college in the town.
- also, could be mentioned ***Intercessors*** (Individuals who talk to different actors with the aim of learning about possibilities for collective action, cooperation, partnerships, and institutional change by learning about the beliefs, material interests, mandates, responsibilities, capabilities and resources of specific actors) – several organisations/persons could be recognised here:

1- Inner processes within dwelling – each staircase leader and House Council Chairman was speaking one by one to all flat owners and often several times.

2- Outer processes – looking outside for consultancies: visiting specialised solar/heating etc. expositions, meeting solar panel experts (planners, builders), heat supply experts.

f) ***Other: energy auditor*** (individual expert) which provides the decision on the project. Building company, which did the project, included the necessity for communication with flat owners as flats were partially closed during the building process.

3.3. Driving factors for MAB renovation governance

When looking for the driving factors for the MAB cases, such as type of energy citizenship and initiating changes and step-wise achieving their goals, making particular achievements towards both democratisation and particularly the practical change of the energy system, the following four factors should be easily mentioned in relation to multi-apartment buildings, as from experience of this particular case.

The first basic factor - ***motivation and preparedness.*** Most important initially is the interest and perceived need for change for those with limited standard living conditions for multi-apartment building flat owners, living in almost never-renovated Soviet-era multi-apartment buildings, being in the situation of slowly degrading those dwellings further. Also, there's the issue of energy resource expense reduction, obviously. Motivation is to be followed by readiness to act individually and as MAB inhabitants' group.

Second factor – ***co-funding availability and applicability.*** Sure, to be mentioned is availability of main/various co-funding possibilities at the national level (actually, ERDF funding) and possibly co-funding at the local level. Also, legal conditions for that funding applicability to the existent types/situations of dwellings.

Third and main success driving factor – ***municipal intermediary management.*** Availability of such municipal management company 'Valmiera Housekeeper' is taking most of the MAB energy renovation project preparation and management load. There are also similar but private companies in the town, taking care of their MABs and renovation works if inhabitants' interest appears or is co-created.

Fourth driving factor – ***environmental/climate-friendly awareness.*** As in the case of this MAB, but also in general, there are certainly to be recognised the growing interest and understanding of changing socio-economic conditions for quality life in MAB, even if it may not be first as environmental/climate awareness. These processes are to be widely/selectively/actively facilitated from national/local management levels, including more effective demonstration of such success cases as this MAB-RS18 case.

4. MAB renovation: internationalization context

Renovation of multi-apartment buildings in Latvia, co-financed by EU funds (ERDF), started in 2009. Within two planning periods (2007-2013 and 2014-2020), around 1400 multi-apartment buildings are renovated, of which 620 buildings (22,8 thousand apartments, around 4% of Latvia's total apartment number) are in the 2016-2024 period. After renovation, the 'B' energy efficiency class is achieved on average.

Findings (Kazukauskas & Li, 2024; Kudreņickis et al., 2024a) indicate that upgrading existing MABs to meet 'B' class energy performance in the Baltic states requires investment and a long-time payback period, and the internal rate can even be negative; the same is indicated by (Galvin, 2024b; Hirvonen et al., 2022). Thus, such renovation in Latvia's economic current conditions is hardly possible without the public/EU (ERDF) grant part.

In the first phase (Kudreņickis et al., 2024a) of the EnergyProspects project, energy-efficient MAB renovations in Latvia have been analysed, and the results of the 2016-2024 national programme of MAB renovations have been analysed, providing in-depth analysis of energy savings and related costs. In general, the energy efficiency improvement (improvement of specific thermal energy consumption after renovation project implementation) on average is high, 60+%; however, it is achieved with a high specific cost per saved kWh and a long (around 30 years) payback time. The specific saving costs depend on the MAB type (construction series, number of apartments); particularly, the specific saving costs for small-scale MABs (3-9 apartments) are significantly higher than average ones; thus, the number of renovated small MABs within the national programme was very low. These significantly higher specific costs in the case of small MABs (3-9 apartments) renovations require for these buildings the rooftop solar facilities as the instrument to increase the economic viability of the renovation project and must be evaluated first.

Also, it was found that ~60% of MAB renovations have been done by flat owners established housing associations, as opposed to the municipal housing enterprises' led MAB renovation cases still being in the game too. Various installations of renewable energy technologies complementary to MAB renovation are still rare in practice. Both these situations confirmed our interest in the second phase of the study focusing in detail on a practical example where both aspects have been successfully carried out.

The justification of the high energy efficiency investments must be found. One of the justifications for high energy efficiency investments is to consider additional benefits, such as better comfort, improved health conditions and, due to it, avoided health costs and improvement of labour productivity, or the general promotion of economics bringing an overall positive impact on household budgets. In research studies during the last years, these energy efficiency benefits are actively discussed.

For instance, the average price of a CO_2 allowance (one tonne) in the EU Emission Trading System auctioned for Latvia in 2023 was 83.5 EUR (Ministry of Climate and Energy of the Republic of Latvia, 2023), and thus the total annual price of CO_2 mitigated within the project can be evaluated at around 2 thousand EUR, which for 15-year renovation measures' technical lifetime contributes around 11% of project costs. The CO_2 mitigation impact is limited by the high already existing renewables share in the district heating system.

Regarding health impact, the study (Chatterjee & Urge-Vorsatz, 2021) has evaluated that a German worker can gain 5.2 productive days a year, while a Hungarian worker can gain 2.2 days, by avoiding sick days after living in high-efficiency buildings. Applying the average figure of 3.7 days per Latvia and 130-295 EUR cost per day (Preiss & Klotz, 2008), it can be calculated as 480-1090 EUR annual savings for workers. Cautiously considering 30 working-age residents in the building, this sum corresponds to 5.4-12.3% of the project costs.

However, all these are indirect benefits. In its turn, the addition of rooftop solar technologies can provide a direct positive impact on the MAB upgrade project.

Conclusions

MAB renovation case documentation and building and governance process with rooftop solar technologies in Valmiera was studied, including its **governance process cycle and framework preconditions and driving factors,** also in the general context of national and local energy governance.

1. Rooftop solar technologies and aspects of their installation are rather actively studied in Baltic states' research, as we have shown in literature analysis; however, there is the gap between scientific research and practical implementation and especially for rooftop solar PV technologies in Latvia.

2. This gap shows that MAB resident communities themselves are unlikely to be sufficient drivers for the implementation of rooftop solar technologies. For such development a coordinated facilitating framework is needed at both state and municipal levels.

3. In the currently ongoing MABs renovation programme within Latvia's EU Cohesion Policy Programme for the 2021-2027 planning period, increased ERDF support intensity (above general support intensity) has been planned to be provided for rooftop RES technologies. The expected national support programme, financed by the Modernisation Fund, which will provide support for zero-emission RES technologies in both MABs and energy communities, can be a significant facilitator.

4. At the municipal level, the support provided by municipalities for increasing the energy efficiency of MABs is important. However, the application of real estate discounts for rooftop solar technologies is a rare practice (not available in the Valmiera municipality either) or applies to solar PV, not solar thermal panels.

5. The rooftop solar technologies can provide a significant share of thermal energy for domestic hot water preparation and electricity energy consumed by the MAB residents, 50+% depending on the type of MAB (number of floors, number of apartments, etc.).

6. The literature overview shows the most attention is paid to solar PV panels. The interest in solar PV panels, in a great sense, is caused by the development of energy communities. In its turn, despite the range of valuable studies that are in place, the STCs seem to be 'undeservedly forgotten'. The optimal combination of both thermal collectors and PV panels may maximise the benefits.

7. However, the studies (Galvin, 2022; Rehman et al., 2022) also call for being rational and installing the on-site rooftop technologies on a scale which is optimal from the technical and economic points of view – namely, the objective 'net zero energy building' shall not be self-interest due to the fact that physically the electricity exchange with the power grid will take place in dominating cases. The gap between 'optimal self-production' and zero energy building' is rational to be covered by the overall decarbonisation of the power supply system, including that residents might also be members of the renewable energy community owing/operating off-site facilities.

8. Analysed Valmiera case study included complex multi-apartment building renovation measures together with the installation of rooftop solar thermal collectors (14.74 kW), significantly improving building energy performance and reducing thermal energy consumption and CO_2 emissions.

The case confirms that rooftop solar technologies can provide an important contribution to domestic hot water preparation, covering approximately 60–70% of annual hot water energy demand during the operating season. However, the up-to-now (very) rare deployment of rooftop solar technologies in Latvia's MABs, compared to the solar PV panels boom in single-family buildings, shows the imperfections also in national-level governance instruments.

9. The mainstreaming of solar energy in MABs must be part of the overall national strategy for both mainstreaming renewable energy in buildings in general and the national buildings' renovation plan. In any case the target shall be met by the interaction of top-down (national to municipal) and bottom-up (starting with local champions) initiatives.

10. For the MABs energy renovation process (project) there shall be built and implemented necessary **energy efficient renovation governance framework,** to be potentially constructed by the complementary triple governance dimensions framework model, applied here as analytical governance process studies tool, and, subsequently, these dimensions can be seen as the energy renovation process success **preconditions.**

10.1. **Governance stakeholders' dimension precondition.** The set of all stakeholders' groupings (governance segments) to be involved are house inhabitants/association, municipality, municipal housekeeping service-project management company, and, of course, also international-national funding institutions. Additionally, there shall be stressed the role of the last stakeholders grouping of mediators - all four local/regional mediators (media, educators, NGOS's, science-knowledge institutions-experts) as for this particular renovation case pre- and up to post-project facilitation, but also, generally, for the whole municipal energy renovation development process communication (information, education-training, participation, pro-environmental/climate behavior).

10.2. **Governance content dimension precondition.** One of the reasons for the municipalities and state's limited renovation cases success rate has been that the other multiple thematic sectoral benefits provided by energy renovation and also rooftop solar technologies are not fully recognized and utilised. Besides general social-ecological systems approach application, there are different particular sub-sectors where additional benefits can be achieved.

10.3. **Governance instruments dimension precondition.** The whole set of governance instruments established and to be applied in complementarity manor – from national legislation and further on local municipal policy and legal bylaws, planning documents and process instruments, economic-financial, also infrastructure-technological, particularly, institutional-administration instruments, and finally the communication instruments. All parties involved are stressing the crucial role of established **communication processes and instruments,** and further **collaborative approach** development.

11. From the experience of this particular case, **critical localized driving factors** were identified also. The first initial and basic factor - motivation and preparedness. Second factor – co-funding availability and applicability. Third and main success driving factor – municipal intermediary management. Fourth driving factor – stepwise growing environmental-climate-friendly awareness.

In the project practice it means: the strategic availability
of European Regional Development Fund (ERDF) and municipal co-funding, active resident participation, localized household leadership, and a robust municipal intermediary management system - exemplified by the municipal property management enterprise 'Valmieras Namsaimnieks' (Valmiera Housekeeper).

12. Technical and engineering excellence alone cannot solve the residential energy efficiency gap. Successful multi-apartment building renovations require a **complete, lifecycle-based governance process** (governance process cycle incl. consecutive initial situation-system analysis, followed by policy design and planning, management and monitoring, even also post-project monitoring and management) **structured by triple governance dimensions framework** of governance stakeholders, governance content and governance instruments, municipalities can translate climate policies into community-led, solar-integrated building transitions.

Acknowledgements

The Latvia case study presented has been supported by the University of Latvia and funded by the EU Horizon 2020 programme (Grant agreement ID:101022492) as an integral part of the project 'EnergyProspects'. Acknowledgments also extend to all local stakeholders involved, national, international project collaborators.

Abstract
This study assesses policy arrangements and implementation practices related to water resources and agricultural governance developments in Latvia, focusing on the agriculture-water governance framework supporting nature-based water retention and general policy coherence. The research combines analysis of national policy and legal frameworks with a case study of the Dviete River basin, a floodplain landscape characterised by seasonal flooding, intensive agriculture, and Natura 2000 protected areas. The assessment comprised two stages: (1) top-down approach as a multi-sectoral, multi-level governance analysis within the EU Horizon OPTAIN project framework and (2) bottom-up approach as a multi-stakeholder assessment of local/regional governance, and both stage studies were realised at all governance levels and in the Dviete River basin. Case studies research included document studies, visual evaluations, stakeholder mapping and a deep semi-structured stakeholder interview. Interviews were conducted in two stages with altogether 39 representatives of key policy sectors and all governance levels from the public environmental/nature protection, water and agriculture sectors, municipalities, entrepreneurs/farmers, NGOs and others. Existing policies were considered inadequate, and respondents emphasised insufficient cooperation among all main stakeholders mentioned, alongside administrative complexity, limited cost-effectiveness, weak communication, voluntary implementation, and weak control systems. Key governance gaps included fragmented legislation, limited administrative capacity, inadequate funding, insufficient technical support, and low awareness. Effective implementation of water retention and general water-agricultural harmonisation towards policy coherence in Latvia is constrained less by the legislation limitations than by fragmented governance – weak cross-sectoral coordination, insufficient stakeholder collaboration, and poor integration of complementary governance instruments across governance levels.
Keywords: water governance, policy coherence, cross-sectoral collaboration, agricultural governance.

Introduction

In the European Union (EU), water resource governance is determined by a complex set of policies that involve both environmental and agricultural areas. These policies establish both regulatory and economic instruments. The Water Framework Directive (2000/60/EC) (WFD) (European Parliament & Council of the European Union, 2000), the Nitrates Directive (91/676/EEC) (Council of the European Union, 2026), the Common Agricultural Policy (CAP), and the Floods Directive provide a broad regulatory structure; however, research indicates (Platjouw et al., 2023; Nilsson et al., 2012; Pereira Dos Santos et al., 2025) that significant challenges persist in implementation, particularly regarding policy coherence across policy sectors and governance levels. Policy coherence between different sectors is one of the most important issues in water and agricultural management. Studies emphasise that this coherence should be assessed not only between water policy instruments but also between water, biodiversity, and agricultural sectorial policies (Platjouw et al., 2023) and an even wider list of governance sectors directly and indirectly involved or to be involved, particularly environmental sectors and climate adaptation governance (cross) sectors (Ernsteins et al., 2025). However, in practice, potential inconsistencies between different directives and policy instruments still exist. For example, while the Nitrates Directive contributes to the WFD objective of preventing the deterioration of water bodies, its objectives do not always fully align with the WFD's objectives of achieving a satisfactory ecological status for water bodies (European Commission, 2025).

Policy coherence across policy areas is one of the major challenges in water and agricultural governance. The OECD (2025) defines policy coherence as 'the systematic promotion of mutually reinforcing policy actions across government departments and agencies, creating synergies towards achieving the agreed objectives'. This approach means that policy instruments in different sectors should be mutually coordinated and aimed at achieving common policy objectives. Furthermore, this definition suggests that coordinating policy instruments across sectors is essential for achieving common policy objectives. However, achieving policy coherence is often difficult because of conflicting political policies, designs and stakeholders' interests and the way institutions are divided across different policy areas (Nilsson et al., 2012).

Agricultural policy significantly influences the quality and availability of water resources. The effectiveness of water resource management relies on the alignment of water policy instruments with agricultural policies, a basic relationship again highlighted by the OECD (2025). CAP significantly impacts agricultural practices across the EU—yet a recent study (Platjouw et al., 2023) indicates that agricultural subsidy systems may, in certain cases, undermine environmental goals. The financial components of the CAP may obstruct the objectives of the WFD and the Nitrates Directive.

Although the 2023–2027 CAP places greater emphasis on environmental sustainability, recent research (Pereira Dos Santos et al., 2025) indicates that direct support for river restoration remains limited. Existing

eco-schemes and agri-environmental measures provide only partial support, while many restoration measures remain underfunded, lack a coherent EU-wide approach, and are insufficiently aligned with broader freshwater restoration objectives.

The coordination of institutions is a critical determinant of policy effectiveness. The effectiveness of policy implementation is closely related to policy capacity, which Wu et al. (2017) define as 'the competencies and capabilities important to policymaking'. Furthermore, policy capacity encompasses the analytical, operational, and political skills needed to create and implement policies at different levels of government.

Furthermore, the importance of multi-stakeholder governance and stakeholder engagement is growing, alongside existing regulatory frameworks. Research suggests that addressing complex environmental issues requires the active involvement and cooperation of various stakeholders (Nilsson, 2012; Nesheim et al., 2021; Glavan et al., 2022). Even environmental NGOs have a long-standing history and well-developed practices, including also lobbying for environmental policies in the EU and nation-states; the establishment of multi-stakeholder platforms is now getting a new wave in the rise, thereby actively facilitating dialogue among institutions, researchers, farmers, and other relevant parties. These platforms serve to integrate scientific understanding with local expertise, consequently fostering the creation of solutions tailored to the unique conditions of a given territory. However, EU legislation supports, but does not prescribe, specific participatory mechanisms but rather requires Member States to ensure public participation, resulting in opportunities for local actors to influence policymaking.

Environmental governance research emphasises that effective policy implementation depends not only on regulatory frameworks but also on the entire range of instruments, particularly governance structures and stakeholder interactions. In this context, a generic triple governance dimensions framework model was proposed (Ernsteins et al., 2017), consisting of three mutually complementary systems of governance dimensions: governance stakeholders (who), governance content/sectors (doing what), and governance instruments/processes (how), all interacting during an environmental governance process cycle – these triple dimensions altogether form an integrated governance system frame for both analysing existent governance processes and framing within complex socio-ecological systems, but first of all, serving/building a governance framework for decision-makers and practitioners.

Governance sectors (content/domains) refer to the environmental thematic areas addressed within environmental governance, which increasingly extend beyond traditional environmental pollution and infrastructure, biodiversity/nature and resource protection and rational use sectors to non-traditional environmental health, communication and climate change governance sectors. Furthermore, there are integrated linkages with socio-economic sectors (e.g., agriculture, forestry, tourism, culture) within a broader sustainable development governance perspective.

Governance stakeholder groups refer to the main societal actors involved in or influencing environmental governance, etc. According to Ernsteins et al. (2017), this framework identifies five stakeholder segments: the state, municipalities, businesses, general society/households, and four complementary mediator groups (media, educators, NGOs, and academia), which facilitate stakeholder and governance subsystem interaction, information and knowledge exchange, participation, and pro-environmental behaviour at local, regional, and national levels.

Environmental governance also integrated water resource governance/management (IWRM) uses governance instruments, as the policy and implementation tools and methods applied to put governance into management practice. These instruments comprise a spectrum of interrelated elements intended to address the institutional, socio-economic, and technical facets of governance. The complementary governance instrumental framework includes policy & legislation, planning, institutional & administrative, economic & financial, infrastructure & technology, and communication & collaboration instrument groupings (Ernsteins et al., 2017).

Effective governance, therefore, requires both horizontal integration between sectors and vertical integration across governance levels, supported by active involvement of multiple stakeholder groups, possessing various instrumental possibilities. Collaborative governance and stakeholder communication play an essential role in bridging science, policy, and practice and supporting sustainable environmental decision-making (Ernsteins et al., 2017; Nesheim et al., 2021).

The findings of policy and document analysis confirm that in Latvia water resource governance takes place at multiple levels stipulated by national laws, Cabinet of Ministers regulations and policy planning documents; even this governance is not fully vertically integrated (Ernsteins et al., 2025).

The Water Management Law introduces an integrated approach to water resources governance based on the river basin management principle (Parliament of the Republic of Latvia, 2002). In turn, Cabinet Regulation No. 834 sets out specific requirements for reducing pollution caused by agriculture, including restrictions on fertiliser use and requirements for the preparation of fertiliser plans (Cabinet of Ministers, 2014).

Latvia employs various, also economic, instruments, alongside regulatory ones, exemplified by the Common Agricultural Policy Strategic Plan 2023–2027, which allocates funds for agri-environmental initiatives and sustainable water resource management (Ministry of Agriculture, 2022). Nevertheless, mirroring challenges faced by other European nations,

the efficacy of policy instruments in Latvia may be constrained by sectoral fragmentation, inadequate data integration, and institutional coordination deficiencies (European Commission, 2025).

The initial examination of environmental governance within the Dviete River basin (Ernsteins et al., 2025) as a case study research area chosen for the current study identified several structural challenges that impede sustainable water resources and landscape management. Research suggests that the water basin is subject to various environmental pressures, including pollution stemming from wastewater, intensive agriculture, seasonal flooding, and inadequate institutional capacity for the management of the Natura 2000 site.

Researchers emphasise the need for a more integrated and adaptable governance framework (Ernsteins et al., 2025); such a framework should strengthen collaboration across different sectors, improve communication and stakeholder involvement, and support grassroots governance initiatives, while potentially receiving institutional support from higher levels. Multi-actor collaboration platforms (Ernsteins et al., 2025; Nesheim et al., 2021) and participatory governance are important mechanisms for improving policy coordination, knowledge exchange, and co-developing locally appropriate environmental management solutions.

Current research is conducted within the framework of the EU Horizon 2020 project OPTAIN (2025) ‘Optimal strategies to retain and reuse water and nutrients in small agricultural catchments across different soil-climatic regions in Europe’ (OPTAIN, n.d.). The project was orientated to improve water and nutrient management in small agricultural catchments across Europe by analysing Natural/Small Water Retention Measures (NSWRM) and their potential to enhance water retention, reduce nutrient losses, and increase climate resilience in EU partner countries and wider afield (Glavan et al., 2022; Lemann et al., 2022). NSWRM are understood as nature-based measures aimed at increasing water retention in the landscape, reducing runoff, improving water quality and enhancing ecosystem services (Magnier et al., 2024).

The overall aim of the OPTAIN project was to identify effective combinations of water retention measures and develop science-based recommendations for their implementation at farm, catchment and national policy levels. The project combines modelling, case study analysis in partner countries and stakeholder engagement to better understand both environmental and governance factors influencing the implementation of these measures.

Within the wider European framework of environmental policy integration, the objectives concerning water management, agricultural production, biodiversity conservation, and climate adaptation are becoming increasingly interconnected. Deliverable 6.2 (OPTAIN, n.d.) of the OPTAIN project assessed the coherence of water and agricultural policies across local, regional, national, and EU governance levels through policy reviews, comparative case studies from twelve European countries, and a survey of policy experts. The findings revealed common governance challenges across countries, including fragmented responsibilities, weak cross-sectoral coordination, insufficient administrative capacity, limited financial and technical support, and inadequate communication and knowledge transfer, all of which constrain the implementation of NSWRMs (Glavan et al., 2022).

Building on these cross-national findings, this study shifts the focus from a comparative European assessment to an in-depth national and local analysis of Latvia. It evaluates how the identified governance challenges and policy integration issues are reflected within the Latvian governance system and the Dviete River basin case study.

Specifically, the study was tasked to investigate the interplay between the water, agriculture, environmental and nature protection sectors (horizontal integration) and the interactions among national, regional, and local governance levels (vertical integration) to potentially assess the coherence of governance arrangements and practices supporting water resources and agricultural policy implementation. In doing so, the study identifies governance gaps and opportunities for strengthening governmental policy coherence and cross-sectoral coordination within the Latvian context.

In the context of the Horizon 2020 project, the current research in Latvia aimed to investigate the governance framework determining the implementation of NSWRM and small river basin water resource governance, with an emphasis on policy coherence and integration across various sectors and governance tiers.

Materials and Methods

Although nature-based water retention measures are implemented primarily at farm and small catchment levels, their successful implementation depends largely on coherent national governance linking the water and agricultural sectors. The Latvian whole-set stakeholder interviews assessment (Ernsteins et al., 2025) likewise indicates that the principal barriers arise from fragmented sectoral policies, insufficient institutional coordination and weak vertical integration rather than from a lack of local willingness to act. Consequently, analysing the governance interactions between the water and agricultural sectors is essential, since local initiatives alone cannot ensure effective and large-scale implementation without coherent national policy, legislation and financial programme support.

The Dviete River basin in southeastern Latvia covers approximately 254 km² (similarly to all other countries’ case areas in the OPTAIN project in Europe), with a river length of 37 km, being a single and comparatively small sub-basin as a contributory part of the Daugava River Basin District (RBD) covering 27057 km² (one of four RBDs in Latvia

according to WFD) and was selected as the case study area in Latvia. The area was selected due to its distinctive nature-culture landscape, including annually long-term formed floodplain waterscape shaped by tensions between agriculture and nature and representing long-standing experience with local bottom-up environmental initiatives.

The seasonal hydrological dynamics of the basin are characterised by extensive annual spring flooding lasting one to three months, largely influenced by the Daugava River water's direct inflow into the Dviete River (Nature Conservation Agency, 2018).

Historically, the area's floodplain was extensively meliorated in the 1930s to support intensive agriculture, establishing a strong agricultural tradition but also contributing to nutrient pollution affecting the Daugava River and ultimately the Baltic Sea. Since the 1990s, gradual nature conservation efforts have been introduced in the area, including the designation of a Natura 2000 site 'Dviete Floodplains' in 2004 (Cabinet of Ministers, 2007) as one of the most diverse and species-rich bird sites in Latvia. Despite several national and international nature protection projects realised within parts of the basin, its governance system and management structures remain non-basin-based, unplanned, largely sectorial and fragmented.

The research is based on a social-ecological systems (SES) research and development (R&D) approach, implemented through a case study research methodology to examine the governance framework supporting NSWRM implementation practice and, actually, wider looking for national governance frames and their functioning, using complementary methods: document analysis, stakeholder mapping, and semi-structured interviews with key stakeholders.

The interviews aimed to obtain stakeholders' perspectives on challenges and potential solutions related to water-use efficiency, the use of water and nutrient management tools and techniques, and the economic sustainability of technologies at farm and catchment levels. It also examined how environmental concerns such as water quality, water quantity, climate change and nature conservation are incorporated into policy and management systems. These empirical data were collected in two complementary research stages during the OPTAIN project – in 2022 and 2025.

The first stage studies (2022)

There was a vertical across administrative levels governance approach applied primarily following a top-down perspective from the national governance level while maintaining a thematic focus on agriculture and water in both mono- and cross-sectoral contexts. Accordingly, interviews were conducted, selecting national-level stakeholders from environmental-nature protection sectors and agriculture-water management sectors representing ministries, and further on, approaching also related regional/municipal governance levels to capture policy design and regulatory frameworks and institutional perspectives influencing NSWRM implementation.

A document analysis was conducted to examine policy instruments, governance responsibilities, and institutional arrangements influencing water and nutrient management and the implementation of NSWRM in Latvia. The analysis covered relevant legislation and policy documents across sectors – agriculture, water governance, nature protection, climate policy, and spatial planning – and governance levels, enabling an assessment of policy coherence.

At the EU level, the analysis included key directives influencing national environmental and water policy, such as the WFD, the Nitrates Directive, the Urban Wastewater Treatment Directive (91/271/EEC), and the Environmental Quality Standards Directive (2008/105/EC). These directives form the basis for national environmental regulation and water governance across EU member states.

For the agricultural sector, the analysis included the Strategic Plan for the Common Agricultural Policy of Latvia 2023–2027, the Law on Agriculture and Rural Development, the Law on Circulation of Fertilisers and the Amelioration Law. Additional relevant Cabinet of Ministers regulations included Regulations No. 834 on protection of water, soil and air from pollution caused by agricultural activities and Regulations No. 600 and No. 776 regulating financial support instruments for environmental and agricultural investments.

For the water resources management sector, the analysis included the Water Management Law, the Law on Pollution, and several Cabinet of Ministers regulations governing water use permits, water quality standards, and the discharge of pollutants. Strategic planning documents included river basin management and flood risk management plans for Latvia's four river basin districts (Daugava, Gauja, Lielupe, and Venta), with particular attention to the Daugava River Basin Management Plan relevant to the Dviete River basin.

Additional legislation included the Law on the Conservation of Species and Biotopes (The Parliament of the Republic of Latvia, 2000) and the Law On Specially Protected Nature Territories (Legal acts of the Republic of Latvia, 1993), together with planning documents relevant to the study area: the Nature Protection Plan for the Nature Park 'Dviete Floodplain' (2020–2032) and Cabinet of Ministers Regulation No. 274 on individual protection and use regulations for the nature park (Cabinet of Ministers, 2007).

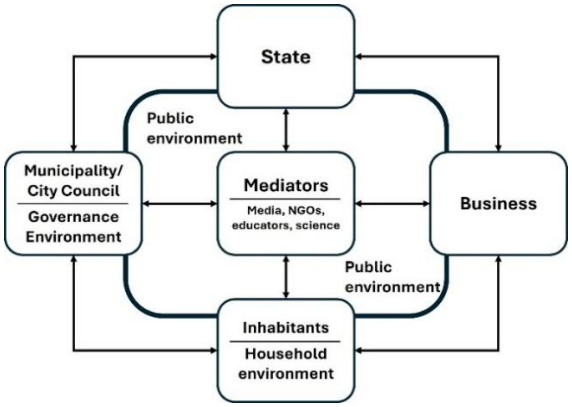
Initial top-down governance-based approach interviews were carried out during Spring 2022 and involved a total of 18 informants. Six respondents represented national policy-making authorities, including the Ministry of Agriculture (three respondents) and the Ministry of Environmental Protection and Regional Development (two respondents), while three informants represented a policy-implementation authority: the Latvian Environment, Geology and Meteorology Centre, responsible for water resources monitoring and planning of River Basin District Management plans

(RBDMPs). Six interviews were conducted with regional-level structures of national authorities and two with municipal, local-level authorities. All participants possessed a high level of policy expertise and were directly involved in action-policy design, legislative development and the preparation of support strategies and financing schemes responsible for policy implementation. All informants hold at least a university master's degree, with expertise in agriculture, water and environmental governance.

Semi-structured in-depth interviews were carried out online via Microsoft Teams, allowing for synchronous audio-visual communication and recording with respondents' consent. Interviews lasted approximately two hours on average. As some ministerial respondents had limited cross-sectoral expertise in NSWRM, several group interviews brought together experts from different policy fields within the same institution to improve response completeness and quality.

The OPTAIN project-designed questionnaire form used in the first studies stage of the research was structured into several thematic blocks starting with respondents' professional background, knowledge and experience with water-related environmental challenges, familiarity with relevant policy frameworks, and then including perceptions of policy compatibility across sectors such as agriculture, water management, environmental protection, spatial planning and climate policy. Additional sections explored governance practices at farm and catchment levels, policy communication to end-users, perceived barriers to implementing water and nutrient retention measures, and possible policy improvements (Glavan et al., 2022).

The second stage studies (2025)



The methodologically complementary design was the second stage (2025) of studies - there was a horizontal across local/regional stakeholders' governance approach primarily following a bottom-up perspective and from the all-set of stakeholders' (Figure 1) points of view on water/environmental governance processes in the particular Dviete River basin and related upper governance levels.

Studies included document analysis, stakeholder mapping and semi-structured in-depth interviews designed to further explore first research stage results, but with particular attention given to all main local Dviete River basin and related sub-regional stakeholders, emphasising a bottom-up approach as, to some extent, opposite but complementary to the first-stage study realised as a top-down approach.

The quintuple network governance structured stakeholder's constellation collaboration model (Ernsteins et al., 2017) was applied, based on an interrelation framework that encompasses five complementary stakeholder group-based segments (Figure 1), namely the state, municipalities, businesses, local residents, and mediators (which include NGOs, educators, academia, and media). Stakeholders were identified and purposively selected for each segment based on their thematic relevance and expertise, ensuring comprehensive coverage of all principal stakeholder groups.

Figure 1

The hierarchically structured collaboration model of 5 governance stakeholder's segments as all existent stakeholders' core groupings (Ernsteins et al., 2017)

In total, in spring 2025, altogether 19 participants representing the whole set of different core stakeholder groupings were interviewed, including representatives of the state sector/national level (3), municipalities (5), businesses (3), civil society (2) and mediators (6). Semi-structured interviews allow for in-depth exploration of stakeholders' experiences, attitudes and perspectives while enabling a multidimensional understanding of environmental governance processes. The interview structure was developed around four interrelated analytical dimensions – the hierarchically structured collaboration governance model (Ernsteins et al., 2017) complementary incorporates governance content/sectors, governance instruments, governance stakeholder groups and governance monitoring-indicator systems, but communication complementary was conceptualised as a cross-cutting component and studied via the information, education, participation and behaviour dimensions model (Ernsteins et al., 2017).

The interviews examined key issues related to the integration of development planning, water and nature protection objectives, possibly cross-sectorial; the application of regulatory and economic policy and all other instruments; all the stakeholder network involvement in decision-making processes; and existing top-down and bottom-up governance monitoring systems and indicators in environmental-nature-water-agri and other sectors' governance.

All interviews were conducted individually, either in person or remotely via telephone, and lasted for about one hour. A pre-developed interview guide structured the discussions while allowing respondents to elaborate on their perspectives and experiences. Interview transcripts were analysed thematically to identify key governance challenges, policy gaps, and opportunities to improve governance and management implementation in the study area.

Results and Discussion

The subsequent chapters synthesise the principal outcomes of the investigation, derived from policy and documents analysis, stakeholder mapping and interviews undertaken during two stages of the study:
- first, multi-sectoral public institutions' governance across all three administrative levels in the country, from the national to the local municipal level in the Dviete basin, - second, multi-stakeholders' network co-governance interests locally within the Dviete River basin area.

Collectively, these findings elucidate the institutional, policy, and governance factors influencing the adoption of water and nutrient retention measures across key stakeholder groups (state, municipalities, businesses, society/households, and mediators), major sectors (e.g., agriculture, water governance, environment, forestry, spatial planning, and related fields), and governance instrument groups: policy & legislation, planning, institutional & administrative, economic & financial, infrastructure/technology, and communication & collaboration.

1. Multi-sectorial public governance studies across administrative levels in Latvia

First-stage findings primarily address the multisectoral governance framework's approaches and impacts on the execution of NSWRM in Latvia. The first research stage analysis, applying the OPTAIN project-designed interview matrix, specifically scrutinises crucial structural policy instruments; legislative stipulations concerning water quality and quantity management; policy compatibility deficiencies and inter-sectoral conflicts; communication strategies with end-users; practical applications of NSWRM tools; and stakeholder-recommended approaches for enhancing policy coherence and implementation.

1.1. Structural policies towards implementation

The CAP Strategic Plan 2023–2027 represents the most significant agricultural policy tool influencing the adoption of NSWRM in Latvia. Interviewed specialists emphasised that the CAP support mechanisms are the primary method through which farmers are encouraged to adopt environmental practices related to water retention and nutrient management. Although the previous CAP programming period supported retention measures across the country, the adoption rates were relatively low, and observable improvements in water quality were limited. Informants highlighted that the new CAP Strategic Plan aims to address these shortcomings by concentrating on nitrate-risk areas with increased precision, particularly within the agriculturally intensive Zemgale region in Latvia. This focused approach aligns national agricultural policy with EU environmental directives and broader Green Deal objectives (European Commission, 2019), including the Farm-to-Fork and Biodiversity strategies (European Commission, 2020a, 2020b). Conversely, several respondents cautioned that the efficacy of these measures will be contingent upon sufficient funding, administrative capabilities, and farmer participation.

RBDMPs represent the main framework for water governance in Latvia. The country is divided into four river basin districts, Daugava, Gauja, Lielupe and Venta, each governed by a mid-term management plan together with a Flood Risk Management Plan (FRMP) that is periodically updated. These plans define mandatory and additional measures for achieving satisfactory ecological status of water bodies, based on assessments of water quality, water quantity, sectoral pressures and spatial planning impacts. Informants noted that RBDMPs provide important strategic guidance for implementing water management measures, including those related to nutrient retention and ecosystem restoration.

However, a structural governance limitation was also identified. RBDMPs are approved at the ministerial level rather than by the Cabinet of Ministers, which limits their cross-sectoral binding force. As a result, coordination between water management objectives and other policy domains, such as agriculture, spatial planning and nature protection, remains weak. Several informants described the plans as important strategic frameworks but emphasised they are not compulsory for all sectors involved in water management.

1.2. Legislation: Water Quality-Quantity, Nutrients

The legislative framework addressing water quantity and water quality challenges is extensive but unevenly integrated across sectors. Informants generally considered that legislation addresses excess water challenges, such as flooding, to an intermediate or high degree. Flood protection measures are primarily treated as planning and civil protection issues rather than being integrated into ecosystem-based water retention or landscape-scale water management strategies.

The link between NSWRM and spatial planning is weak and occurs mainly through RBDMPs. Because these plans are approved at a ministerial rather than governmental (Cabinet of Ministers) level, their formal authority across other policy domains remains limited. Consequently, spatial planning processes do not systematically incorporate water retention measures or ecosystem-based solutions.

Conversely, agricultural legislation demonstrates a comparatively robust integration of nutrient management, primarily through the establishment of manure management regulations and the enactment of the Nitrates Directive. Informants emphasised that the stipulations governing fertilisation planning, manure storage, and livestock density establish explicit benchmarks for nutrient management in the agricultural sector. Nevertheless, the institutionalisation of nutrient recovery from streams and landscape-scale nutrient retention strategies is less pronounced. While certain retention measures are included in river basin plans, especially in nitrate-sensitive areas, these measures are largely programmatic in nature, lacking the force of binding legislation.

Water quantity regulation focuses mainly on water

abstraction permits and environmental resource taxes, which apply when water extraction exceeds 10 m³ per day. While these instruments control water use, they do not actively promote retention or ecosystem-based water management approaches. Similarly, drought management is not strongly reflected in current legislation, and informants noted that regulatory mechanisms addressing water scarcity remain limited.

Most NSWRM measures remain voluntary. Some practices, such as artificial wetlands, reduced tillage and precision fertilisation technologies, are supported through CAP financial instruments. However, informants emphasised that uptake remains limited due to weak financial incentives and insufficient CAP funding for agri-environmental measures. For example, only a small proportion of identified potential sites currently receive financial support for implementation.

Key structural barriers identified by informants include legislative gaps, policy incoherence between sectors, fragmented land ownership and insufficient trust and engagement between institutions and landowners.

1.3. Policy Compatibility and Cross Sectors

Significant incompatibilities exist between agricultural and forestry objectives and the goals of nature conservation, water management and climate policy. Informants frequently highlighted that sectoral policies pursue different priorities, creating structural tensions in land-use governance.

Key horizontal conflicts include tensions between nature protection and climate strategies, where climate-driven land-use measures such as afforestation may conflict with biodiversity conservation objectives. Drainage (amelioration) systems represent another major source of conflict. These systems increase agricultural productivity but may negatively affect wetlands and ecosystem restoration efforts.

Afforestation and forest intensification policies may also contradict habitat protection goals, while river regulation and riverbank cleaning can improve hydraulic flow but damage protected habitats. Buffer zones along water bodies, which are important for nutrient retention, are often perceived by farmers as reducing productive agricultural land. Spatial planning conflicts also occur when settlement development is permitted in flood-prone areas, contradicting water management and climate adaptation objectives.

These sectoral conflicts reflect broader governance challenges related to insufficient horizontal policy integration. Informants emphasised that coordination between agriculture, water management and nature protection sectors remains limited. At the catchment level, these compatibility gaps become more visible, particularly in interactions between agricultural policies, water governance and spatial planning.

Informants also highlighted that climate–water integration remains weak due to limited locally specific data on climate impacts at the catchment scale. Improved policy synergies therefore require stronger cross-sectoral coordination, enhanced monitoring and hydrological modelling, and a revision of technical standards for drainage systems to ensure compatibility with biodiversity and ecosystem protection.

1.4. Communication: complementary instruments

Environmental communication is not only about transferring information but also about promoting knowledge exchange, engagement, and behavioural change as part of communication process cycle. Therefore, communication instruments play an important role in education, training, strengthening public participation, and encouraging environmentally responsible behaviour (Ernsteins et al., 2017). Their effectiveness relies on collaborative, results-oriented approaches that foster social learning, behavioural change, and stakeholder involvement.

Low farmer interest and limited uptake of available funding were frequently linked by informants to insufficient understanding of the economic benefits and long-term cost-effectiveness of NSWRM for farm development. Although several policy instruments promote environmentally friendly practices, policy communication to end-users remains insufficient.

Communication practices were described as mainly reactive, with information often provided only upon request. While advisory services and project-based seminars exist, much policy information is distributed through web-based platforms that are extensive but difficult for users to navigate.

Informants noted that improving the implementation of retention measures requires stronger advisory support and awareness-raising activities demonstrating the potential ‘win-win’ benefits of NSWRM, combining improved farm productivity, long-term economic stability and environmental protection.

Existing knowledge-sharing networks could play a greater role in improving policy communication. These include agricultural advisory services, river basin management boards acting as multi-stakeholder platforms, and local intermediaries such as nature guides. Public participation processes related to local nature protection planning and LEADER-supported rural development initiatives were also identified as underutilised opportunities for stakeholder engagement.

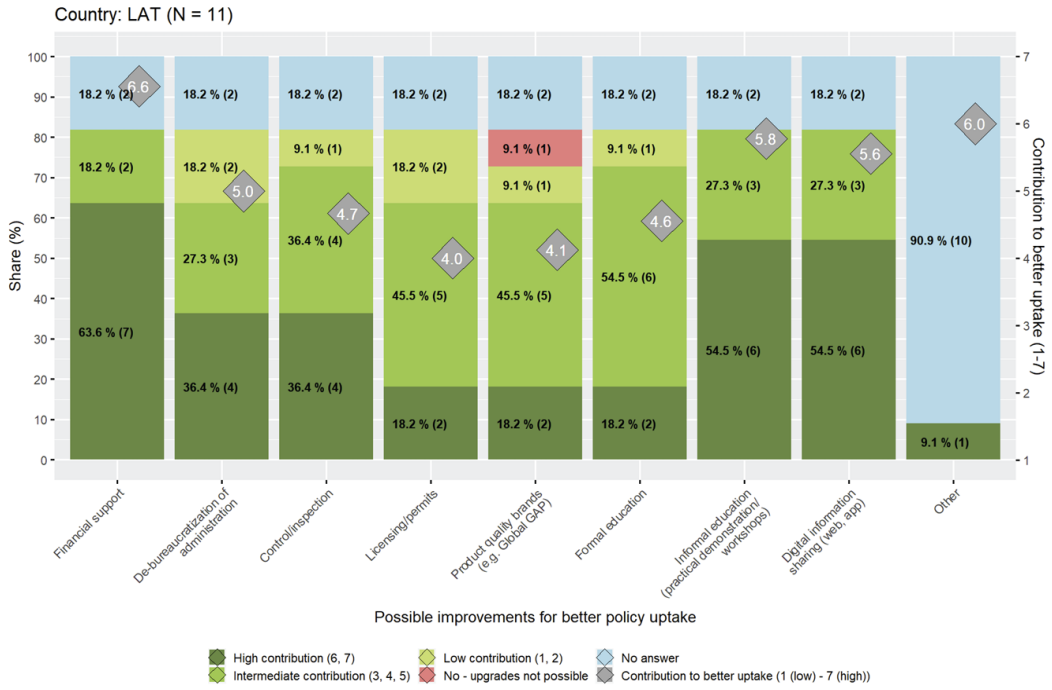
Informants further emphasised that establishing open educational platforms and structured training programmes addressing agriculture, forestry, water quality and climate issues could significantly improve knowledge exchange and strengthen policy integration from national objectives to farm-level practice.

1.5. Instrumental techniques for NSWRM

The use of specific tools and techniques for implementing NSWRM varies significantly across sectors. In agriculture, several practices are already widely recognised as important for improving water quality and reducing eutrophication. These include green cover crops, meadows and pastures, buffer strips and hedges, crop rotation and low-tillage practices.

Informants reported that many stakeholders have

practical experience with agricultural and hydro-morphological measures, although implementation levels differ depending on local conditions and financial support availability. Most respondents also indicated that they had addressed issues related to excess water management, water quality improvement and nature conservation in their professional work, while experience with drought management and in-field water retention measures was more limited.



Examples of nutrient recovery from aquatic ecosystems also exist, although these measures are typically implemented primarily for nature conservation purposes rather than water management objectives. For instance, lake ecosystem restoration through reed cutting has been used to restore habitats for protected bird species while improving water quality conditions.

1.6. Instruments for compatibility and implementation

This section presents the solutions suggested by informants to address compatibility issues and improve the implementation and acceptance of measures. The respondents evaluated different policies and legislative changes aimed at encouraging the use of water and nutrient retention measures; see Figure 1. Within the governance instrument framework shown in Figure 1, the analysis focused on various instrument types, including financial support, reducing administrative bureaucracy, control and inspection methods, licensing and regulatory processes, product quality brands, formal education, informal education, digital information, and other supportive measures. The analysis is based on the OPTAIN D6.2 methodology (Glavan et al., 2022), which combines cross-sectoral survey data from stakeholders, case study analysis across multiple European countries, and quantitative evaluation using Likert-scale-based assessments to identify key barriers and improvement pathways.

Figure 1

Information provided by the informants as response to the question on how to upgrade policy/legislation for improved uptake implementation of water and nutrient retention measures in Latvia (Glavan et al., 2022)

Additional qualitative suggestions from informants highlight several governance improvements needed to enhance the implementation of water and nutrient retention measures. Respondents emphasised strengthening the legislative framework, including government approval of RBDMPs to ensure their measures become binding and properly financed. They also suggested increasing environmental fines to discourage rule violations. Improved cross-sector coordination was identified as essential, particularly through spatial planning that aligns sectoral priorities and integrates environmental, agricultural, and regional development objectives. Informants also stressed the importance of clearer stakeholder responsibilities, better consultation between agricultural experts and farmers, stronger cooperation platforms for NGOs and authorities, and increased environmental awareness.

Enhancing administrative capacity and policy instruments constituted a further critical area of focus. Informants suggested the establishment of a user-centric national monitoring system, designed to facilitate efficient data exchange and to bolster evidence-based decision-making processes. Furthermore, the reduction of administrative burdens and the enhancement of information accessibility were deemed essential for promoting the adoption of environmental measures. Increased financial backing,

particularly compensatory subsidies for agricultural limitations such as buffer zones, was recognised as a vital incentive. Furthermore, stakeholders pointed out the need for enhanced technical assistance, which included improved access to geospatial data, more detailed guidance on the planning and design of water retention strategies, and a stronger focus on educational programmes, training initiatives, and awareness campaigns.

Following the initial findings, recommendations were directed toward specific environmental issues, including water quality, water availability, biodiversity preservation, and climate change mitigation. Participants emphasised the necessity of prioritising interventions that would most effectively improve water quality, refining fertiliser and manure management practices on farms, and reinforcing the importance of buffer zones and sustainable agricultural methods. For water quantity management, respondents highlighted the importance of integrating flood risk management with basin planning and maintaining melioration systems to improve water retention and soil productivity. Additional recommendations included expanding compensation schemes for protected habitats, improving spatial planning to reflect environmental restrictions, and strengthening information and policy support related to climate change mitigation and adaptation.

2. Multi-stakeholder's network studies for local co-governance in the Dviete River basin area

Second-stage findings primarily address cross-stakeholder, cross-sectoral, and cross-instrumental governance in the Dviete floodplain, focusing on institutional fragmentation, stakeholder perspectives, policy coordination, communication, and implementation of nature-based water and nutrient retention measures across governance levels.

2.1. Governance: comparative studies across Europe

Comparative case studies across Europe indicate that environmental objectives are frequently present in policy frameworks but remain weakly integrated in practice (Glavan et al., 2022). In Latvia, this situation is illustrated by the absence of explicit legal references to NSWRM in water legislation and the programmatic rather than binding nature of many retention measures within river basin management planning. Likewise, flood protection measures and spatial planning initiatives exhibit a tenuous relationship with ecosystem-based water management strategies. These observations corroborate prior investigations indicating that environmental governance structures frequently encounter challenges in achieving cross-sectoral integration, notwithstanding the presence of common policy objectives. Regional analyses additionally underscore variations in policy priorities, which are contingent upon specific hydro-climatic contexts.

Despite the availability of various policy instruments, such as the CAP Strategic Plan and RBDMPs, their execution frequently suffers from a lack of robust coordination mechanisms spanning different governance tiers and policy areas. This fragmentation is not exclusive to the Latvian context.

The findings of this research underscore several structural governance impediments that hinder the effective execution of NSWRM in Latvia. These challenges largely reflect observations from wider European assessments undertaken within the OPTAIN project (Glavan et al., 2022). Specifically, the Latvian context exemplifies fragmented governance, particularly among the water governance, agricultural, nature conservation, and climate policy sectors.

In Pannonian and continental areas in Europe, the focus is primarily on water scarcity and the management of droughts; conversely, boreal regions prioritise water quality and the mitigation of nutrient runoff, as noted by Glavan et al. (2022). Latvia's governance structure mirrors this emphasis, with nutrient management receiving more explicit attention in its legal framework, particularly through regulations pertaining to nitrates and the management of manure. However, broader landscape-scale nutrient retention and ecosystem-based governance measures remain weakly institutionalised.

2.2. Governance: towards cross-stakeholder collaboration

During the initial phase of the study, a stakeholder mapping and situational audit were conducted in the Dviete River basin within the OPTAIN Project framework to identify relevant actors for the interview process and analyse their potential roles in environmental governance. Based on the upgraded quintuple Helix stakeholder framework, stakeholders were grouped into five interconnected categories: state institutions, municipalities, businesses, mediator groups, and society. The mapping revealed a diverse but weakly interconnected stakeholder landscape, highlighting the need for targeted communication, collaboration platforms, and supportive governance mechanisms to strengthen cross-sectoral cooperation in water, nature, and agricultural management.

Another important challenge concerns the practical uptake of retention measures by land managers and farmers at their farm level. The results indicate that most NSWRM practices in Latvia remain voluntary and rely heavily on CAP-based financial incentives. Limited funding availability and insufficient advisory support significantly reduce the adoption of such measures. Similar barriers have been identified in other European case studies, where financial instruments, administrative complexity and limited guidance hinder the implementation of water and nutrient retention measures at the farm level (Glavan et al., 2022).

2.3. Governance: towards cross-sectoral collaboration

Cross-sectoral collaboration within the governance of the Dviete floodplain, as revealed during the second research stage by an analysis of interviews spanning five stakeholder segments, such as state institutions, municipalities, entrepreneurs, local society, and

mediators, demonstrates a formal existence, yet its practical application is inconsistent and structurally disjointed. Despite a shared recognition of the necessity to reconcile nature conservation, agricultural practices, and economic advancement, the interviews expose considerable disparities in the actors' interpretations of problem origins, governance frameworks, and the allocation of responsibilities.

Initially, governance fragmentation surfaces as a primary concern across all sectors. This fragmentation manifests in insufficient horizontal coordination between policy domains and institutions. Interviews with representatives of the state sector indicate that responsibilities related to environment, water management, and nature protection are divided among several institutions and ministries, which complicates coordinated decision-making. As a result, planning instruments and monitoring systems exist, yet their practical implementation is often limited by political priorities, institutional capacity, or insufficient funding. Similar concerns are raised by municipal representatives, who note that responsibility for managing protected areas is often shared between state institutions, local governments, and landowners, but these responsibilities are not always clearly defined.

Overall, the interview analysis suggests that the key challenge in cross-sectoral governance of the Dviete floodplain is not the diversity of interests itself, but rather the lack of effective coordination mechanisms and stable collaborative structures. While there is broad recognition across sectors of the need to integrate environmental protection, agriculture, and regional development objectives, achieving effective collaboration requires clearer institutional frameworks, long-term financing mechanisms, and more targeted communication between institutions and local communities. Without such instruments, cross-sectoral cooperation remains fragmented and largely dependent on individual initiative rather than systematic governance practices.

2.4. Governance: towards cross-instrumental collaboration

Different stakeholder groups prioritised very different governance instruments: state institutions → planning & monitoring; municipalities → spatial planning and institutional capacities; farmers/businesses → financial & technical support; NGOs/mediators → communication & participation. All six governance instrument groups are necessary: legal–political, planning, institutional–administrative, economic–financial, technological, and communication & collaboration instruments.

Representatives from state institutions primarily highlighted the significance of institutional coordination mechanisms, planning instruments, and monitoring systems as crucial elements in floodplain management; however, they also acknowledged the limitations imposed by the fragmented nature of ministerial responsibilities and collaboration limitations.

Municipal officials underscored the necessity of more explicit delineation of responsibilities and the enhanced incorporation of environmental goals within spatial planning and local development initiatives, as well as the growth of municipal capacities (esp. territorial administrative and management units). Local business owners and land managers/farmers, conversely, often prioritise pragmatic and economic considerations, specifically the demand for dependable financial instruments and enduring funding strategies that would facilitate the implementation of environmentally focused land and water management practices, which also require necessary infrastructure - technological instruments (also NWRSM) as well as related information and training instruments. Simultaneously, mediators and representatives of the local communities stressed the importance of communication, stakeholder engagement, and collaborative platforms designed to foster improved cooperation between governmental bodies and local communities.

Communication and the dissemination of knowledge instruments are definitively crucial elements affecting the efficacy of policy implementation. In Latvia, policy communication tends to be predominantly reactive, and the information provided frequently presents navigational challenges for its intended audience. Consequently, this situation hinders the acknowledgement of the prospective economic and environmental benefits linked to NSWRM, thus contributing to restricted engagement in funding endeavours. Prior European research also underscores that improved communication strategies, advisory frameworks, and knowledge-sharing networks are crucial for augmenting farmer participation and facilitating the implementation of sustainable land and water management practices (Glavan et al., 2022).

2.5. Governance: triple governance dimensions frame

These governance challenges are also reflected in the comparison between the two interviews and other studies' stages conducted in this study. The initial interview stage employed a top-down methodology, engaging primarily with representatives from national and regional public institutions and municipalities. The interviewees highlighted challenges related to structural policy and governance, such as policy fragmentation, administrative difficulties, and insufficient coordination between different sectors. In contrast, the following second interview stage took a bottom-up approach, focusing on the perspectives of local stakeholders. Here, these structural issues manifested practically through ambiguous responsibilities, restricted communication, and fragmented collaboration at the local level.

Effective governance requires an integrated application of the triple governance dimensions: cross-sectoral, cross-level, and multi-stakeholder governance, supported by communication and monitoring.

These findings are also consistent with the conclusions of the environmental governance audit of the Dviete

River Basin conducted previously (Ernsteins et al., 2025), which similarly identified fragmented governance, weak horizontal and vertical integration, limited monitoring, and insufficient stakeholder coordination as key barriers to effective environmental governance management. Both studies emphasise that improving governance effectiveness requires stronger integration and complementary application of governance instruments, a SES approach, enhanced environmental communication, and the development of collaborative platforms that support both bottom-up engagement and coordinated top-down support.

The results, in summary, also corroborate several pivotal conclusions presented in OPTAIN Project Deliverable 6.2. Successful execution of water and nutrient retention strategies necessitates more robust horizontal policy integration across various sectors, improved coordination among different governance tiers, and more effective support systems for agricultural producers and landholders. Furthermore, translating policy goals into tangible environmental improvements require enhanced monitoring, communication, and stakeholder collaboration. Strengthening these governance dimensions would support more integrated and effective water and agricultural policy implementation in Latvia and across Europe.

Conclusions

1. Water and agriculture governance harmonization imperative. The results of policy and document analysis, stakeholder mapping and interviews highlight key challenges and opportunities related to policy arrangements and practice implementation, pointing to water and agriculture governance harmonisation as imperative in Latvia. While perceptions of governance effectiveness, regulatory burden, and sectoral responsibilities vary across stakeholder groups, the interviews collectively highlight several key structural issues in cross-sectoral cooperation and environmental governance.

2. Fragmented water and agriculture governance. The agriculture-water governance framing landscape could currently be characterised by systemic deficiencies within existing policy frameworks, encompassing fragmented and inconsistent legislation, inadequate cross-sectoral collaboration, and a lack of administrative capacity, expertise, and technical assistance. Funding mechanisms frequently prove insufficient or misdirected, and awareness-raising and communication initiatives are often restricted, thereby impeding the effective integration of water and agricultural governance.

3. Horizontal and vertical integration dependency. Effective implementation depends on stronger horizontal integration between water, agriculture, biodiversity and climate policies, together with improved vertical coordination across national, regional and local governance levels. Despite existing coordination mechanisms (e.g., between the Ministries of Agriculture and Environment), cross-sectoral and vertical cooperation remains insufficient for coherent policy arrangements.

4. Imperative: overarching water and agriculture governance framework. Overall, the findings indicate that improving individual policy instruments alone is insufficient. Effective implementation of NSWRM and general river water basin management requires an overarching governance framework, and for this role, stakeholders qualitatively tested governance framework integrating the triple governance dimensions - multi-stakeholder, cross-sectorial, multi-instrumental governance process across all governance levels.

5. Stakeholder engagement and tailored communication instrumentarium. Although advisory actors and support structures are present, access to information and knowledge, particularly for water retention practices, remains limited for farmers, constraining effective practice implementation in agricultural systems. Information exchange alone is insufficient, and it must be complemented by targeted training, participatory approaches, and practical demonstrations and behaviours, e.g., the all-quadruple communication instruments. And instruments shall be selectively adjusted and tailored to each stakeholder's core grouping and subgroups, which is essential for improving knowledge exchange, increasing awareness and supporting bottom-up implementation.

6. The whole set of governance instruments. Stakeholders prioritise each different governance instrument group according to their public functions and roles: state institutions focus on coordination and planning instruments, municipalities on clearer responsibilities and spatial integration, businesses on financial instruments and stability, and civil society on communication and cooperation instruments.

Achieving effective governance and local implementation, potential harmonisation requires not only a balanced combination of the whole set of complementary governance instruments (legal-political, planning, institutional-administrative, economic-financial, infrastructure-technological, and communication & collaboration instruments) but also their coordinated development, planning, and implementation rather than fragmented application.

7. Innovation, technical and financial support programs. Although advisory structures exist, access to knowledge, innovation and technical support remains limited, particularly for farmers implementing water retention measures. Increased financial support, together with improved information exchange, informal education and digital tools, was identified as the highest priority for strengthening implementation capacity.

8. Governance sectors and socio-ecological systems approach. Stakeholders identified excess water as the main agricultural thematic challenge, whereas water scarcity, in-field water retention, and nutrient recovery receive comparatively limited attention. Also, the SES

approach is not only known for traditional environmental pollution and infrastructure sectors, biodiversity and nature resources sectors, but also non-traditional environmental health, communication and, particularly, climate change governance sectors, as well as integrated linkages with socio-economic sectors.

9. Imperative policy coherence for integrated water resources and agriculture governance and management practice. Effective implementation of water retention and general water-agricultural harmonisation towards policy coherence in Latvia is constrained less by the legislation limitations than by fragmented governance – weak cross-sectoral coordination, insufficient stakeholder collaboration, and poor integration of complementary governance instruments across governance levels. Furthermore, administrative complexity, weak enforcement, voluntary implementation, and unfavourable cost-benefit ratios further constrain practice implementation. At the same time, bottom-up initiatives increasingly contribute to practice implementation and even local policy coherence developments, especially where institutional capacity is limited.

Acknowledgements

The Daugavpils University in partnership with University of Latvia, supported this publication, though the general data used here for the first stage studies was gathered within the EU Horizon project OPTAIN research funded and done in Latvia, being contributed by main stakeholders of the Dviete River Basin area and region.

Abstract
This study analyses the development and spatial transformation of built-up areas in Lithuania and its counties over the period from 2005 to 2025. A combination of quantitative, comparative, grouping, categorization, and classification methods were applied to systematically examine patterns of urban expansion. Statistical data from the Land Fund of the Republic of Lithuania (2005–2025) and Eurostat (2022, 2025) were used to assess changes in the extent of built-up areas at both national and county levels, alongside demographic indicators such as population number. The results indicate that in 2025, built-up areas in Lithuania covered a total of 248,550.05 ha, corresponding to 3.81% of the national territory, with the largest proportions recorded in Vilnius (5.13%) and Kaunas (5.08%) counties, and the smallest in Tauragė (2.74%) and Utena (3.01%) counties. Analysis of population density and compactness demonstrated that the highest values occurred in Vilnius, Kaunas, and Klaipėda counties, reflecting concentrated and intensive urbanisation, while peripheral counties exhibited more dispersed, low-density development. The overall compactness of built-up areas in Lithuania in 2025 was 12.29 inhabitants/ha, indicating medium-density urbanisation and a mixed urban structure. Between 2005 and 2025, the total built-up area in Lithuania increased by 67,966.42 ha (37.64%), with the fastest relative expansion observed in Klaipėda (77.49%) and Utena (46.63%) counties, highlighting regional disparities in urban growth and spatial development patterns.
Key words: built-up area, change in built-up area, compactness of built-up areas.

Introduction

The expansion of built-up areas and urbanization in major cities and regions is a key topic in contemporary urban studies. Urban growth is influenced by population dynamics, planning priorities, and long-term economic trends, and it significantly transforms landscapes in ways that are often long-lasting and difficult to reverse (Seto et al., 2011; Angel et al., 2011; Liu et al., 2020; Chen et al., 2024).

Urbanization does not occur uniformly. In some cities, expansion spreads at low density into suburban areas, while in others, construction intensifies within existing urban zones, increasing population density. These processes are driven not only by housing demand and the need for services but also by broader factors such as economic development, market distribution, and population mobility (Batty, 2024; Frolking et al., 2024).

Advances in technology have greatly enhanced the monitoring of built-up areas. High-resolution satellite imagery (Sentinel, Landsat, PlanetScope), remote-sensing tools, and advanced data-processing methods now provide precise insights into the dynamics and trends of urban expansion. Large-scale geospatial platforms allow for long-term analyses and comparative studies of urban transformations across cities, regions, and countries (Gorelick et al., 2017; Li et al., 2020, 2024).

The environmental impacts of urban growth are increasingly evident. Expansion disrupts natural landscapes, degrades soil quality, threatens biodiversity, and alters hydrological patterns, particularly in sensitive areas such as wetlands and natural meadows (Grimm et al., 2008; McKinney, 2009; Alberti et al., 2016). These changes often lead to increased flood risk, higher local temperatures, and altered microclimates, with effects that are long-term and frequently irreversible (Zhou et al., 2016; European Environment Agency, 2016).

Climate change mitigation has become an increasingly important issue today. Climate change affects the natural environment, rural areas, and urban systems, making it essential to understand how urbanization influences environmental conditions. Previous studies indicate that the expansion of built-up areas has significant impacts on ecosystems, physical structures, and the social environment. Therefore, development management decisions must be comprehensive and directed toward the sustainable development of territories (Ramanauskas et al., 2024).

Urbanization occurs at varying rates and under different regulatory frameworks worldwide. Rapid, loosely regulated growth is common in parts of Africa and Asia, often linked to new infrastructure development (Cobbinah & Aboagye, 2017). Conversely, European and North American cities tend to emphasize compact urban layouts, redevelopment of underused land, and more intensive land use (Schneider et al., 2010; Haaland & van den Bosch, 2015).

In the Baltic countries, suburban expansion frequently converts agricultural land into residential areas, creating fragmented and uneven landscapes (Feranec et al., 2017; Listauskas & Valčiukienė, 2018). Capitals such as Vilnius and Riga illustrate this trend, where development often outpaces the capacity of planning systems, altering spatial structures and local environments (Bardauskienė & Pakalnis, 2012; Krišjāne at el., 2012).

According to Pereira et al. (2025), both population changes and territorial planning issues are evident in Lithuania and its suburban areas. An analysis of land-use changes in the country's major cities—Vilnius, Kaunas, and Klaipėda—reveals a decline in

agricultural land and an increase in forested and built-up areas. These trends highlight the particularly complex transformation of urban territories and the landscape structure across the country.

Rapid urbanization has led to various territorial planning challenges, particularly when green or natural infrastructure is not effectively integrated into urban spatial frameworks. Ramanauskas et al. (2025) highlight that high-density development and extensive surface sealing adversely affect quality of life. Therefore, the expansion of built-up areas must be accompanied by deliberate planning measures that prioritize the incorporation and development of green spaces.

The development of natural infrastructure, such as green spaces, is an objective achieved through the sustainable planning and management of territories. It also underscores the critical interrelationship between society, the environment, and the economy. In highly urbanized areas with limited or no green space, the impacts of climate change and related challenges become particularly pronounced, including frequent and intense storms, heat waves, and excessive or insufficient precipitation (Aslanoğlu et al., 2025).

Long-term land-cover studies show a steady increase in urbanized areas, particularly in suburban zones. Effective planning and institutional oversight are essential to ensure that urban expansion occurs in ways that protect environmental quality, maintain landscape integrity, and benefit local communities (UN-Habitat, 2020).

Growing concerns about uncontrolled urbanization have highlighted the importance of planning principles that promote environmental protection, green infrastructure, and compact urban forms (Kabisch et al., 2017; Keskin et al., 2013). Cities investing in interconnected green and natural systems benefit from improved microclimates, reduced flood risk, and other positive outcomes (Feltynowski et al., 2018). Scenario modeling is increasingly used to evaluate potential development trajectories under varying demographic, economic, and climate conditions (van Vliet et al., 2009).

Not all urban areas are expanding; some experience population decline, resulting in abandoned buildings and underused infrastructure (Haase et al., 2013; Martínez-Fernández et al., 2012). These contrasting trends require context-specific strategies. In rapidly growing regions with limited planning capacity, informal or unauthorized construction can further complicate environmental management (UN-Habitat, 2020).

As can be seen from the analysis above, the expansion of built-up areas is driven by interconnected demographic, economic, technological, governance, and environmental factors. Ensuring sustainable urban growth that benefits society while minimizing environmental risks requires continuous spatial monitoring, effective planning, and adaptive policy frameworks (Liu et al., 2014; Wei et al., 2022).

The chosen topic is relevant because analysing changes in the extent of built-up areas helps to reveal ongoing urbanisation processes in the country and its counties. This, in turn, makes it possible to anticipate future trends, prevent emerging planning and environmental challenges, and ensure sustainable territorial development, a high quality of life, and effective environmental management. However, despite the importance of understanding urban expansion dynamics, there is still a lack of detailed, spatially consistent, and up-to-date analyses of how built-up areas have changed over time across different administrative levels in the study region. This gap limits the ability to accurately assess the scale and rate of urbanisation needed for informed planning and decision-making.

The object of this study is the built-up areas of Lithuania.

The aim of the study is to analyse the dynamics of built-up area expansion in Lithuania from 2005 to 2025.

Research objectives:

1. To analyse the current state of built-up areas across Lithuania and its counties.
2. To calculate population density, built-up density, intensity, and urban compactness using standardized spatial formulas.
3. To evaluate the changes in built-up area extent between 2005 and 2025.

Materials and Methods

In order to assess changes in built-up areas from 2005 to 2025, the following statistical data were used: data from the Land Fund of the Republic of Lithuania for the period 2005–2025 (Nacionalinė…, 2005–2025) on built-up areas in Lithuania and its counties, as well as Eurostat data from 2022 and 2025 (Eurostat, 2022, 2025) on built-up areas and demographic indicators in the EU. The study covered the period from 2005 to 2025. Changes in built-up areas and other indicators were analyzed not only at the national level but also across ten Lithuanian counties.

Quantitative analysis methods were employed in the study. Changes in built-up areas were calculated for the country as a whole and for individual counties. During the preparation of the article, population density, the share of built-up areas, and the built-up area compactness index (population per hectare) were also calculated.

The compactness of built-up areas reflects the number of inhabitants per hectare of built-up land, Formula 1.

$$BC = \frac{P}{Ab} \quad (1)$$

where: BC is built-up area compactness (population per hectare, people/ha), P – population (number of inhabitants) and Ab – area of built-up land (hectares).

For the analysis, grouping, categorization, and classification methods were used. *Grouping* was used to organize the statistical data by key analytical

dimensions, including time periods (2005–2010, 2010–2015, 2015–2025), territorial units (Lithuania and ten counties), and thematic indicators (built-up area extent, population, population density, and compactness index). This approach allowed for the identification of temporal trends and spatial patterns in a structured manner.

Categorization was applied to transform continuous quantitative variables into meaningful analytical classes. For instance, built-up area compactness values were categorized into three interpretative levels: low, medium, and high compactness. This procedure facilitated the interpretation of spatial urban structure by simplifying complex numerical distributions into conceptually clear categories that reflect different stages and forms of urban development.

Classification was used to assign observed values and calculated indicators into predefined typologies based on defined threshold values. In particular, the intensity of built-up area change was classified into three development types: intensive (>40%), medium (20–40%), and passive (<20%). This classification enabled the assessment of the magnitude of spatial change and supported comparative evaluation between counties and time periods.

Built-up area compactness data were classified into three categories: low, medium, and high compactness. Low compactness of built-up areas is a spatial characteristic of urban structure that describes low building density and a fragmented, dispersed distribution of buildings within a territory. Such a spatial pattern is often associated with peri-urban zones, suburban expansion, or a dispersed type of urbanisation, and may indicate the dispersion of urbanisation processes and increasing territorial fragmentation.

Medium-density urbanization represents a transitional urban structure in which the city core is relatively dense but is surrounded by lower-density residential and functional zones.

High compactness reflects efficient use of urbanized areas and can facilitate infrastructure development and service planning.

In analyzing changes in built-up areas from 2005 to 2025, three phases were distinguished: 2005–2010 – stagnation, 2010–2015 – rapid increase, and 2015 – 2025 – stabilization with slow growth. The temporal segmentation was based on changes in the rate of built-up area growth identified through comparative trend analysis across sub-periods.

Based on calculations of area changes in hectares and percentages, types of built-up area development intensity were identified: intensive (>40%), medium (20–40%), and passive (<20%). The thresholds between low, medium, and high intensity of built-up area expansion were determined based on land cover change analysis methodologies widely applied in remote sensing and GIS studies (Coppin et al., 2004), as well as in urban expansion assessment research (Seto et al., 2011; Angel et al., 2011), and the European Environment Agency's CORINE Land Cover methodology (EEA, 2019).

A descriptive and comparative statistical analysis was conducted, including comparisons of built-up areas (ha and %), population density, compactness indices, and temporal changes in built-up areas across counties between 2005 and 2025, using Land Fund statistical data (Nacionalinė…, 2005–2025) and Eurostat data (2022, 2025).

In addition to quantitative and comparative statistical methods, the study employed analytical and logical reasoning approaches to interpret spatial and temporal patterns of built-up area change. The analytical approach involved the systematic decomposition of complex spatial datasets into key variables (e.g., built-up area, population density, and compactness indices) in order to identify relationships, trends, and structural differences across counties over the study period (2005–2025). This approach is consistent with spatial analysis principles commonly applied in GIS-based land use research, where multivariate datasets are interpreted to reveal underlying spatial processes (Longley et al., 2015; O'Sullivan & Unwin, 2010).

The logical reasoning approach was applied to interpret results and to derive coherent explanations, such as differences in urban growth intensity among counties. This involved inductive reasoning, where general patterns were inferred from observed data trends, and deductive reasoning, where theoretical concepts of urban expansion and land-use change were used to interpret empirical findings. Such reasoning is widely recognized as a fundamental component of geographic and environmental research, particularly in studies of land-use dynamics and urbanization processes (Lambin & Geist, 2006; Seto et al., 2011).

Results and Discussion

Analysis of Built-Up Area Extent in 2025

According to 2025 data, built-up areas in Lithuania covered 248,550.05 ha, representing 3.81% of the country's total area. Including roads, built-up areas account for 5.45% of the national territory. According to Eurostat (2022), in 2022 man-made or built-up areas represented 4.4 % of the total area of the EU, with variations across individual member states (Eurostat, 2022).

The analysis of the share of built-up areas across ten Lithuanian counties reveals significant regional differences in urbanization. The largest built-up areas were recorded in Vilnius County (49,953.55 ha, or 5.1%) and Kaunas County (41,059.83 ha, or 5.08%), Table 1. In three counties – Vilnius, Kaunas, and Klaipėda – built-up areas account for more than 4.5% of the total county area. These territories represent the main cores of Lithuania, where concentration of population, services, infrastructure, and economic activities drives continuous land conversion from agricultural and natural land to built-up land. The average built-up share in these counties is approximately 5.0%, which is significantly above the

national average of 3.81%, indicating a clear core–periphery urban structure.

In contrast, the lowest values are recorded in Tauragė (2.74%) and Utena (3.01%) counties, which are characterized by dispersed settlement structures and predominantly rural land use. These counties also show a higher proportion of agricultural and forest land, reflecting a less intensive transformation of natural landscapes into urban fabric. Urbanization processes in Tauragė County are not intensive, as the landscape is predominantly agricultural. In 2025, agricultural land in the county covered 246,781.22 ha, or 55.98%, compared to the Lithuanian average of 51.55%. In contrast, forests in Utena County covered 248,691.56 ha, or 34.59% (the national average is 32.86%). The density of built-up areas in these counties is low, reflecting a predominantly rural landscape structure. In the remaining six counties, the share of built-up areas ranges from 3.10% to 3.67%, indicating a medium density of built-up areas.

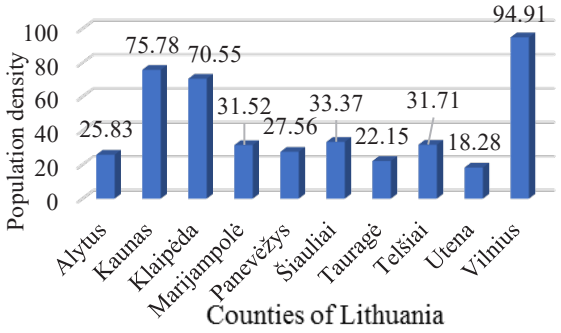
So, the share of built-up areas varies from 2.74% to 5.13%, indicating moderate but clearly differentiated levels of urbanization intensity across the country.

Table 1

Built-Up area of Lithuanian counties in 2025 (ha and %)

Counties	Built-up area (ha)	Built-up area as a percentage of total territory (%)
Alytus	16,700.78	3.08
Kaunas	41,059.83	5.08
Klaipėda	24,898.94	4.77
Marijampolė	16,367.09	3.67
Panevėžys	24,949.51	3.17
Šiauliai	26,439.20	3.10
Tauragė	12,098.51	2.74
Telšiai	14,466.05	3.33
Utena	21,616.59	3.01
Vilnius	49,953.55	5.13

(Nacionaline…, 2005–2025).



From a statistical perspective, the distribution of built-up areas shows a positively skewed pattern, where a few highly urbanized counties (Vilnius, Kaunas, Klaipėda) concentrate significantly higher built-up shares, while the majority of counties cluster around the lower and medium range (3.0–3.7%). This supports a polycentric but uneven urban structure, dominated by strong centers.

Relationship between built-up area share and population density

The analysis of built-up area shares in relation to population density shows that urbanization intensity depends on demographic conditions. The highest population densities were recorded in Vilnius (94.92 inhabitants/km²), Kaunas (75.78 inhabitants/km²), and Klaipėda (70.55 inhabitants/km²) counties, see Figure 1. From this analysis, it is evident that these counties also have the largest shares of built-up areas. Therefore, in counties with the highest populations, economic activities are more developed, and the expansion of built-up areas occurs more rapidly. This confirms a strong positive spatial association between demographic concentration and land conversion intensity.

Figure 1

Population density of Lithuanian counties in 2025 (inhabitants/km²)

Peripheral counties (Utena, Tauragė, Alytus, and Marijampolė) exhibit lower urbanization intensity and have smaller populations, resulting in dispersed built-up areas and lower land-use efficiency. This spatial pattern is closely related to the structure of land cover, particularly the balance between agricultural land and forests.

In these regions, land-use composition shows a dual tendency: while Marijampolė retains a highly agricultural character with 66.5% agricultural land and relatively low forest cover (21.42%), Utena and Alytus demonstrate the opposite pattern, with significantly higher proportions of forested areas (34.59% and 48.09%, respectively) and lower shares of agricultural land (43.73% and 34.9%). Tauragė represents a more balanced but still relatively forest-influenced structure, where forests occupy 32.94% and agricultural land 56.01%.

This distribution suggests that peripheral counties are characterized not only by lower urbanization but also by more heterogeneous land-use systems, where natural and semi-natural landscapes (forests) play a more dominant role compared to intensively cultivated agricultural land. In contrast to central Lithuanian regions, where agricultural land dominates and supports more intensive land management systems, peripheral areas reflect a transition toward less intensive land exploitation and greater ecological continuity.

In the country, the population in 2025 was three million fifty-four thousand five hundred forty-nine (Registrų centras, 2025). In Lithuania, with a population density of 46.79 inhabitants/km² and a 3.81% share of built-up areas, the intensity of urbanization is relatively low.

In 2023, the average population density across the EU was 109 inhabitants per km² although this figure varied

widely among member states. Malta had the highest density, with 1,766 inhabitants per km², followed by the Netherlands (526) and Belgium (387). In contrast, Finland (18) and Sweden (26) recorded the lowest population densities (Eurostat, 2025).

Thus, the analysis indicates that urbanization intensity in Lithuania is lower than the EU average, meaning that residents are less densely settled in built-up areas compared to the European average. In this context, Lithuania occupies an intermediate but low-intensity urbanization position, characterized by dispersed settlement patterns and relatively large shares of agricultural and natural land.

Built-up Area Compactness. The data analysis shows that Vilnius County is characterized by the most compact settlement structure, with the highest built-up area density (18.5 inhabitants per hectare), the greatest overall population density (94.91 inhabitants per km²), and the largest share of built-up land (5.13%), distinguishing it from all other counties in terms of urban concentration and land-use intensity.

At the national level, Kaunas and Klaipėda counties also exhibit relatively high compactness, at 14.93 inhabitants/ha and 14.79 inhabitants/ha, respectively.

Medium compactness of built-up areas was recorded in Marijampolė (8.60), Panevėžys (8.70), Telšiai (9.53), and Šiauliai (10.78) counties, Table 2.

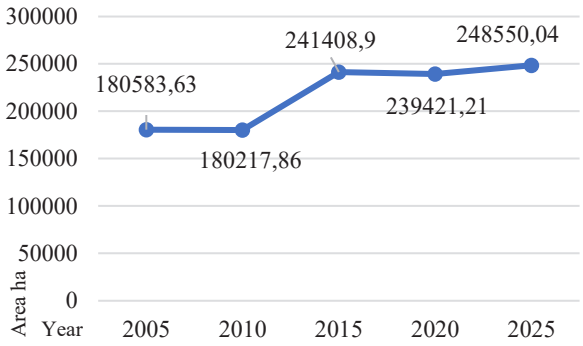
Table 2

Distribution of counties by built-up area compactness categories

Built-up area compactness category	Counties and built-up area compactness (inh/ hectare)	Urban form type	Nature of transformation
Low compactness	Utena (6.08)	Low-density urbanization	Dispersed structure, dominated by single-family houses, weak concentration of urban centers
	Tauragė (8.07)	Low-density urbanization	Sparse, fragmented development with a limited urban structure
	Alytus (8.38)	Low-density urbanization	Dispersed development, dominated by residential houses and homestead-style settlement patterns
Medium compactness	Marijam-polė (8.60)	Mixed-density urbanization	Urban core with low and medium-density zones
	Panevėžys (8.70)	Mixed-density urbanization	Functionally differentiated structure with dominance of the city center
	Telšiai (9.53)	Mixed-density urbanization	Historically formed urban structure
	Šiauliai (10.78)	Mixed-density urbanization	Balanced structure with medium-density built-up areas and peripheral zones
High compactness	Klaipėda (14.79)	High-density urbanization	Compact, multifunctional structure with integrated port and industrial functions
	Kaunas (14.93)	High-density urbanization	Compact urban fabric with active suburban densification
	Vilnius (18.49)	High-density urbanization	Metropolitan structure, highly intensive, with strong functional concentration

The lowest compactness of built-up areas was observed in Utena County, at 6.1 inhabitants/ha. In 2025, built-up areas in Utena County covered 21,616.59 ha, representing 3.01% of the county, with a low population density of 18.28 inhabitants/km². This indicates that Utena County has a low population density and a dispersed urban structure. Low-density urbanization is a form of urban development characterized by a small population spread over a large built-up area, resulting in a scattered and minimally compact urban structure. After carrying out the calculations, it was found that the overall compactness of built-up areas in Lithuania is 12.29 inhabitants per hectare. This value indicates medium-density urbanisation, suggesting that urbanised areas are not excessively dispersed. An analysis of built-up compactness and population density shows a mixed urban structure: concentrated in major cities and their surroundings, and fragmented in peripheral counties.

In Vilnius, Kaunas, and Klaipėda counties, apartment buildings dominate the housing stock. This is associated with a high level of urbanization, strong population concentration, and the Soviet-era development pattern of apartment housing, which has persisted to the present day.



In contrast, in peripheral counties such as Utena, Tauragė, Telšiai, Alytus, and Marijampolė, single-family houses are predominant. In these regions, single-family dwellings typically account for 65–85% of the total housing stock, while the share of apartment buildings is significantly lower.

For example, in Utena and Alytus regions, single-family houses often exceed the 70% threshold.

Changes in the extent of built-up areas in Lithuanian counties, 2005–2025

An analysis of changes in the extent of built-up areas in Lithuanian counties between 2005 and 2025 (in hectares) shows that counties containing major cities – Vilnius, Kaunas, and Klaipėda – experienced the most consistent and greatest expansion of built-up areas. In Šiauliai, Panevėžys, and Telšiai counties, the expansion of built-up areas was uneven: the area increased rapidly until 2015 and then stabilized, Figure 2.

Figure 2
Changes in the extent of built-up areas in Lithuania, 2005–2025 (ha)

Source: (Nacionalinė…, 2005–2025).

Although demographic indicators declined throughout the entire period in Utena and Alytus counties, intensive development still occurred, indicating inefficiencies in territorial structure and a tendency towards urban fragmentation.

As shown in Figure 2, changes in built-up areas in Lithuania during 2005–2025 were uneven, and three distinct stages can be identified: 2005–2010 – stagnation; 2010–2015 – rapid growth; and 2015–2025 – relative equilibrium with slow growth.

This pattern is supported by the data: built-up areas accounted for 180,583.63 ha in 2005 and remained nearly unchanged in 2010 (180,217.86 ha). A sharp increase was observed in 2015, reaching 241,408.90 ha, followed by a slight decrease and stabilization in 2020 (239,421.21 ha), and a modest increase again in 2025 (248,550.04 ha).

Interval-based data analysis indicates that the most rapid expansion of built-up areas in Lithuania occurred during 2010–2025, amounting to 61,191.04 ha, or 33.95%. Overall, analysis of changes in the extent of built-up areas in Lithuania between 2005 and 2025 shows that the analysed area increased by 67,966.42 ha, or 37.64%.

The analysis of changes in the extent of built-up areas (ha) revealed that Vilnius County experienced the largest increase, amounting to 14,744.87 ha.

In contrast, the smallest absolute expansion occurred in Tauragė County, where built-up areas increased by 2,797.18 ha, Figure 3.

Figure 3
Changes in the extent of built-up areas in Lithuanian counties, 2005–2025 (ha)

	Alytus	Kaunas	Klaipėda	Marijamp	Panevėžys	Šiauliai	Tauragė	Telšiai	Utena	Vilnius
2005	11107.53	33477.38	14028.63	11662.42	19939.62	21120.36	9301.33	9995.02	14742.66	35208.68
2010	11149.53	33919.51	13333.45	11579.71	19215.9	21529.05	9301.32	9968.46	14755.46	35465.47
2015	16055.19	40217.07	23134.97	16675.7	25620.29	26571.25	12285.98	14203.23	21037.86	45607.36
2020	16064.12	40352.73	23266.04	16259.84	24692.22	25718.58	11811.16	14029.63	20913.55	46313.34
2025	16700.78	41059.83	24898.94	16367.09	24949.51	26439.2	12098.51	14466.05	21616.59	49953.55

Source: (Nacionalinė…, 2005–2025).

Analysis of the data presented in Table 3, expressed as percentages, shows that during 2005–2025 the extent of built-up areas increased by 77.49% in Klaipėda County and by 50.36% in Alytus County. These represent the highest urbanisation indicators in the country over the analysed period.
The lowest percentage growth in built-up areas was recorded in Kaunas County (22.65%) and Panevėžys County (25.13%).

Table 3
Changes in the extent of built-up areas in Lithuanian counties, 2005–2025 (ha and %)

Counties	Changes in built-up areas (ha)	Changes in built-up areas (%)
Alytus	+5,593.25	+50.36
Kaunas	+7,582.45	+22.65
Klaipėda	+10,870.31	+77.49
Marijampolė	+4,704.67	+40.34
Panevėžys	+5,009.89	+25.13
Šiauliai	+5,318.84	+25.18
Tauragė	+2,797.18	+30.07
Telšiai	+4,471.03	+44.73
Utena	+6,873.93	+46.63
Vilnius	+14,744.87	+41.88

Based on the observed changes in built-up area extent during 2005–2025, the author of this study identified the following types of change.

- >40% – intensive change (Vilnius, Klaipėda, Alytus, Marijampolė, Telšiai, Utena counties);
- 20–40% – moderate change (Kaunas, Šiauliai, Panevėžys, Tauragė counties);
- <20% – passive change.

The study found that intensive and moderate expansion of built-up areas predominated across Lithuanian counties.
The analysis revealed that the expansion of built-up areas in Lithuania during 2005–2025 was uneven. Vilnius, Kaunas, and Klaipėda counties experienced the highest intensity of development and exhibited high compactness, while in other counties urbanisation increased in relative terms but the areas remained more dispersed.
Future expansion of built-up areas will depend on political factors (taxation, subsidies, development strategies), economic factors (job creation, investments in real estate and infrastructure, demographic growth), social factors (population needs, standard of living), and planning factors (legal framework, including laws and building permits, as well as territorial planning documents).
Based on the data and analysis of changes in built-up area extent during 2005–2025, it can be expected that counties containing major cities – Vilnius, Kaunas, and Klaipėda – will remain the primary centres of urbanisation. Expansion is likely to occur both within the cities themselves and in suburban areas and surrounding county districts. In other counties (Utena, Telšiai, Alytus, Marijampolė), development will also continue, with growth in residential quarters and suburban areas. Therefore, future development is expected to involve both residential and commercial areas, along with supporting infrastructure.

Conclusions

1. In 2025, built-up areas covered 248,550.05 ha, accounting for 3.81% of the national territory. The largest built-up areas were recorded in Vilnius County (49,953.55 ha or 5.13%) and Kaunas County (41,059.83 ha or 5.08%), while Tauragė (2.74%) and Utena (3.01%) counties had the smallest share.
2. The highest population densities were observed in Vilnius (94.92 inhabitants/km²), Kaunas (75.78 inhabitants/km²), and Klaipėda (70.55 inhabitants/km²) counties, where built-up area expansion was also the fastest. Utena (18.28 inhabitants/km²), Tauragė (22.15 inhabitants/km²), and Alytus (25.83 inhabitants/km²) counties had low population densities and a dispersed urban structure.
3. The analysis of built-up area compactness revealed that Vilnius County stands out with the highest compactness at 18.5 inhabitants/ha. Kaunas and Klaipėda counties also exhibit high density (14.93 and 14.79 inhabitants/ha, respectively). The lowest population densities per hectare were recorded in Utena (6.08 inhabitants/ha) and Tauragė (8.07 inhabitants/ha), while the national average compactness is 12.29 inhabitants/ha, indicating medium-density urbanisation.
4. Analysis of changes in built-up area extent during 2005–2025 reveals that the total built-up area in Lithuania increased by 67,966.42 ha, or 37.64%. The largest absolute increase occurred in Vilnius County (14,744.87 ha), but the smallest in Tauragė County (2,797.18 ha). In percentage terms, the fastest urbanisation took place in Klaipėda (77.49%) and Utena (46.63%) counties.

Abstract
This study examines changes in agricultural land areas in Lithuania between 2005 and 2025, focusing on their spatial distribution, dynamics, and structural characteristics across all ten counties. The main objectives were to evaluate the current state of agricultural land, analyze its temporal changes over two decades, and identify the main factors influencing these transformations. The study is based on data from the National Land Service of Lithuania covering the period 2005–2025. Both absolute values (hectares) and relative shares (%) of agricultural land by county were analyzed. Agricultural land dynamics were assessed for the years 2005, 2010, 2015, 2020, 2025. Counties were classified according to the intensity of agricultural land change: rapid decrease, moderate change, or relative stability. In 2025, agricultural land in Lithuania covered 3,365.699.61 ha, representing 51.55% of the national territory. The largest shares of agricultural land were recorded in Marijampolė (66.49%), Šiauliai (61.46%), and Panevėžys (60.23%) counties, while the smallest shares were observed in Alytus (34.89%), Vilnius (38.55%), and Utena (43.73%) counties. During the period 2005–2025, the total agricultural land area decreased by 117,246.88 ha (3.37%). The most significant reductions occurred in Vilnius, Utena, and Alytus counties. Structurally stable agricultural land patterns were observed in Kaunas, Marijampolė, Tauragė, and Telšiai counties. The decline of agricultural land is driven by urbanization, suburban expansion, infrastructure development, land-use changes, economic factors, decreasing agricultural intensity, ecological conditions, and regional characteristics. The results indicate that intensive agrarian landscapes are likely to persist in structurally stable regions, whereas more urbanized and environmentally constrained areas may continue to experience agricultural land loss.
Key words: agricultural land, the intensity of change, area changes.

Introduction

The European landscape is shaped by various factors, among which agriculture plays a significant role (Jerrentrup et al., 2017), encompassing agricultural land such as arable land, meadows, natural pastures, and orchards. These areas are used for crop and livestock production as well as other agricultural activities. Agricultural practices include soil preparation, irrigation, sowing, planting, crop management, pest control, harvesting, and other related activities (Farmonaut, 2025b).

Research on changes in the structure of agricultural land is an important field of study (Yan-gang, 2009). Land-use changes are driven by economic, social, legal, biophysical, and various environmental factors. These changes have a significant impact on landscape structure and function (Yan-gang, 2009; Baessler & Klotz, 2005; Xian-jin, 2002; Chun-me, 2014; Reulier et al., 2018). Assessing land-use change trends helps to identify patterns of transformation in agricultural areas and supports the development of sustainable land-use policies (Yan-gang, 2009; Gniadek et al., 2019; Yazdanpanah et al., 2025).

Scientific literature indicates that changes in agricultural land use are driven by a complex interplay of economic, social, and environmental factors, with economic development, urbanization, and climate change identified as particularly influential (Food and Agriculture Organization, 2017; Intergovernmental Panel on Climate Change, 2022). Land use and land cover change studies emphasize that these processes extend beyond purely agrarian transformations and reflect broader landscape dynamics closely linked to socio-economic development (Lambin et al., 2001; Foley et al., 2005; Verburg et al., 2013). Agricultural land is frequently converted into urban areas, forests, or natural habitats depending on regional political priorities, economic conditions, and planning frameworks. Economic growth and market demand play a central role, as land is often reallocated to more profitable uses or adapted to changing consumption patterns and population dynamics. In addition, structural changes such as labor migration, farm consolidation, and shifts in agricultural practices significantly reshape land-use patterns. These transformations increasingly occur at multiple spatial scales, including the global level, with important implications for food security, ecosystem functioning, and the sustainability of landscapes (Rong & Fu, 2023).

Economic factors are among the primary drivers of changes in agricultural land use (Chun-me, 2014). Key influences include low productivity, declining farm profitability, and the conversion of agricultural land into urbanized areas in pursuit of higher economic returns. These processes are further shaped by limited financial capacity to develop farming activities, the effects of economic sanctions and inflation, unemployment, and insufficient income from agricultural production. Income disparities among low-income farmers may encourage their withdrawal from the agricultural sector and a transition toward alternative economic activities. Research indicates that farming costs, gross income, land ownership structure, labor allocation, access to capital, infrastructure quality, and market accessibility are critical economic factors influencing changes in agricultural land use

(Agricultural…, 2025).

Climate change and natural environmental processes also exert a significant influence on the structure of agricultural land. Scientific studies demonstrate that variability in climatic conditions alters land suitability for agricultural activities, compelling farmers to reallocate land to different crops or abandon portions of cultivated land altogether. Such decisions often represent adaptive responses to changing climatic conditions (Tahmasebi et al., 2020).

Processes of farm intensification and diversification are evident in the use of agricultural land (Xian-jin, 2002; Li & Wang, 2002). For example, in China, between 1988 and 2009, the area of arable land decreased significantly, while orchards and forested land became concentrated in more favorable locations (Sha-sha et al., 2013). Globally, since 2001, the total area of arable land has increased by approximately 80 million hectares (5%), whereas permanent meadows and pastures have decreased by 150 million hectares (Food…, 2025). The intensive use of agricultural land depletes natural resources, alters landscapes, contributes to deforestation, and increases greenhouse gas emissions.

Urban expansion is a major factor contributing to the loss and fragmentation of agricultural land (Farmonaut, 2025a). Driven by population growth and economic development, productive agricultural areas are increasingly converted to other land uses, including residential zones, industrial facilities, and urbanized spaces (Xian-jin, 2002; Yazdanpanah et al., 2025).

The structure of land ownership has changed significantly, particularly in post-socialist countries (Lerman et al., 2003; Rusu & Simionescu, 2014; Moravcová et al., 2016; Valtenbergs et al., 2018). In Latvia, an increasing share of agricultural land is owned by legal entities, often with foreign capital, whereas land owned by foreign individuals represents only a small proportion (Valtenbergs et al., 2018). Land reforms and the restoration of property rights, as in other former socialist countries, aim to adapt agricultural structures to current needs (Moravcová et al., 2016). Farm sizes have also changed; in some regions, such as Poland, the number of very small and very large farms has increased (Sikorska et al., 2008).

Transformations in land use have significant impacts on ecosystem services. For instance, the conversion of agricultural land to non-agricultural areas, such as urbanized zones, or the reduction of pastures can negatively affect biodiversity and disrupt natural ecosystem processes. This is highlighted in several review studies analyzing the environmental impacts of land-cover changes (Foley et al., 2005; Newbold et al., 2015; Hasan et al., 2020).

Long-term agricultural practices, including the application of organic and chemical inputs, significantly influence soil properties by altering the structure and functioning of microbial communities. Research shows that ecologically managed land tends to support greater microbial diversity than chemically intensive systems, leading to improved soil quality characterized by higher levels of organic carbon, nitrogen, and microbial biomass (Chaudhry et al., 2011). Nevertheless, soil degradation—manifested through compaction, loss of structure, nutrient depletion, and salinization—remains a major challenge for sustainable agriculture (World…, 2024).

In addition to environmental impacts, changes in agricultural land structure are closely linked to social and economic processes. These transformations often contribute to population migration, shifts in rural employment, and the restructuring of farming practices. Such changes can have significant implications for food security and the economic resilience of farmers. Comparable land-use transformations are observed globally, ranging from structural changes within European Union countries to intensive land-use dynamics in Southeast Asia. Together, these studies demonstrate the complex and interrelated nature of social, economic, and environmental drivers that shape and continuously modify agricultural land-use structures (Appelt et al., 2022).

However, despite the growing body of research, there remains a clear knowledge gap regarding the integrated assessment of how these interacting drivers jointly influence medium- and long-term spatial patterns of agricultural land structure at regional scales. Most existing studies tend to focus on individual drivers (e.g., economic, climatic, or urbanization processes) in isolation or emphasize either global-scale assessments or localized case studies, limiting the ability to generalize results across different socio-spatial contexts. Furthermore, fewer studies explicitly link land-use structural changes with combined socio-economic outcomes and ecosystem responses within a unified analytical framework. Addressing this gap is essential for improving understanding of the multi-dimensional processes shaping agricultural landscapes and for supporting more coherent and sustainable land-use policy development.

Research object is agricultural land.

Objective of the study is to analyze changes in agricultural land areas in the Republic of Lithuania between 2005 and 2025.

Study tasks:

1. To analyze the current state of agricultural land areas;
2. To examine changes in agricultural land areas in Lithuania and its counties from 2005 to 2025;
3. To assess the causes of changes in agricultural land areas.

Materials and Methods

The study focuses on the distribution and dynamics of agricultural land in the Republic of Lithuania, covering all ten counties. The analysis considers both absolute areas (hectares) and relative shares (%) of agricultural land within each county, as well as changes over the period 2005–2025.

The primary data were obtained from the National Land Service of Lithuania (Nacionalinė…, 2005–2025), which provides comprehensive records on agricultural land areas. Absolute agricultural land areas and relative shares were tabulated by county for 2025, and counties were ranked according to both absolute agricultural land and its share of the total area.
To assess spatial differences in agricultural land use across Lithuanian counties in 2025, a descriptive statistical analysis was applied. The analysis included calculation of:

- relative share (%) of agricultural land in each county,
- absolute values (hectares) of agricultural land,
- ranking of counties based on both indicators,
- range analysis (max–min variation between counties),
- comparative classification of counties into land-use intensity groups based on percentile distribution (high, medium, and low agricultural land share).

For interpretative purposes, counties were grouped using a quantile-based classification approach, where:

- high agricultural land use corresponds to upper quantile values,
- medium use corresponds to interquartile range values,
- low use corresponds to lower quantile values.

This approach allows identification of spatial differentiation patterns in land-use structure and supports interpretation of landscape heterogeneity across Lithuania.
Agricultural land areas for 2005, 2010, 2015, 2020, and 2025 were compared to determine trends. Annual changes were calculated to assess the intensity of agricultural land loss or stability. Based on the magnitude of change, counties were classified into three categories:

- rapid decrease: counties with high annual losses of agricultural land (Vilnius, Utena, Alytus);
- moderate change: counties with intermediate losses (Klaipėda, Šiauliai, Panevėžys);
- relatively stable: counties with minimal annual changes (Kaunas, Marijampolė, Tauragė, Telšiai).

The classification of counties according to the magnitude of agricultural land change was based on the calculated annual rate of change in agricultural land area over the study period. For each county, change values were derived from temporal differences in agricultural land extent and expressed as annual percentage change. To ensure comparability across spatial units, a threshold-based classification approach was applied, which is commonly used in spatial and land-use change analysis for grouping continuous variables into meaningful categories (Slocum et al., 2009). Thresholds were defined based on the distribution of observed values in the dataset, allowing the identification of natural breaks between different levels of change intensity. Accordingly, counties were assigned to three categories: rapid decrease (high negative annual change values), moderate change (intermediate negative values), and relatively stable conditions (minimal or near-zero annual change). This approach enables a simplified interpretation of spatial heterogeneity in land-use dynamics while preserving the underlying variability of the data and facilitating comparative regional analysis.
The relationship between agricultural land, urbanization, and population density in 2025 was examined using typological analysis and scatterplots. The relationship between agricultural land, urbanization, and population density in 2025 was analyzed using typological analysis and scatterplot visualization. Typological analysis classified spatial units (e.g., counties or municipalities) into categories based on agricultural land extent, urbanization level, and population density, identifying homogeneous groups such as highly urbanized high-density and predominantly agricultural low-density areas. Scatterplots were used to explore pairwise relationships, with agricultural land share plotted against urbanization and population density to assess trends, correlations, and potential nonlinear patterns. Together, these methods provided both a structured spatial classification and an exploratory quantitative assessment of land-use–population relationships.
To assess temporal and spatial changes in agricultural land area between 2005 and 2025, a time-series descriptive statistical and change analysis was applied. The method included calculation of absolute and relative changes in agricultural land area at both national and county levels.
To evaluate differences among counties and across time periods, a percentage change comparison approach was used, allowing identification of spatial heterogeneity in land-use dynamics. The results were visualized using a time-series trend diagram.
After conducting an analysis of changes in agricultural land areas, the causes of these changes were identified. Based on observed trends from 2005–2025, projections were made regarding the persistence or reduction of agricultural land in each county, taking into account urbanization pressure, suburban expansion, and demographic characteristics.
The estimated average annual decrease in agricultural land was determined by dividing the total change in area from 2005 to 2025 by the 20-year interval.
To estimate future agricultural land-use dynamics, a second-degree polynomial trend model was applied. The model was used to capture potential non-linear patterns in land-use change over time, allowing for the representation of accelerating or decelerating trends. The general form of the model is expressed as, Formula 1:

$$Y_t = at^2 + bt + c \quad (1)$$

where: Y_t – agricultural land area (ha) at time t; t – time variable (year or sequential time index); a, b, c – coefficients estimated from observed data.
The model was fitted separately for each county to

account for spatial heterogeneity in land-use dynamics. Model parameters were estimated based on observed 2005–2025 data using polynomial trend fitting. The resulting county-specific functions were then used for extrapolation beyond the observed period. Forecasts were generated for the years 2030, 2035, and 2040 by extending the fitted polynomial trend lines. In addition to county-level projections, national-level values for Lithuania were obtained by aggregating the projected county estimates. The modelling approach allows identification of long-term tendencies in agricultural land-use change and differences between regions. The polynomial structure captures non-linear trend behavior, which is particularly relevant for areas affected by urban expansion and land-use conversion processes. The resulting projections are interpreted as trend-based scenario estimates rather than exact predictions. They reflect the continuation of historical dynamics under the assumption that observed patterns persist into the future without abrupt structural changes.

Figures and tables were generated to present the spatial distribution and temporal dynamics of agricultural land.

Results and Discussion

Analysis of agricultural land areas in 2025

In 2025, agricultural land in the Republic of Lithuania covered an area of 3,365,699.61 ha, accounting for 51.55% of the country's territory. This indicates that more than half of Lithuania's land area is used for agricultural activities. The data presented in Table 1 demonstrate substantial differences in agricultural land areas among the country's counties.

Table 1

Agricultural land area in Lithuanian counties in 2025 (ha and %)

Counties	Agricultural land area in 2025 (ha)	Share of agricultural land (%)
Alytus	189,022.42	34.89
Kaunas	450,355.52	55.69
Klaipėda	270,289.10	51.76
Marijampolė	296,902.01	66.49
Panevėžys	474,520.40	60.23
Šiauliai	524,731.29	61.46
Tauragė	246,781.22	55.98
Telšiai	223,523.37	51.39
Utena	314,486.43	43.73
Vilnius	375,087.85	38.55

Source: (Nacionalinė…, 2005–2025).

A county-level analysis reveals a clear spatial gradient in agricultural land use intensity. The highest proportions of agricultural land were observed in Marijampolė County (66.49%), Šiauliai County (61.46%), and Panevėžys County (60.23%). These territories form a coherent high-intensity agricultural core of Lithuania, characterized by fertile soils, favorable relief conditions, and long-established agrarian specialization, which collectively support extensive agricultural production systems.

A second group of counties, including Tauragė (55.98%), Kaunas (55.69%), Klaipėda (51.76%), and Telšiai (51.39%), demonstrates a more balanced land-use structure. In these regions, agricultural land remains a dominant component; however, it coexists with significant urban, forested, and semi-natural areas. This indicates a transitional landscape type where agricultural functions are integrated within more heterogeneous spatial systems.

The lowest shares of agricultural land were identified in Alytus (34.89%), Vilnius (38.55%), and Utena (43.73%) counties, where a larger proportion of the territory is occupied by forests, lakes, protected areas, and urbanized zones – particularly in Vilnius County. Consequently, the share of agricultural land in these counties is comparatively smaller.

When agricultural land areas are examined in absolute terms (hectares), the largest areas were recorded in Šiauliai (524,731.29 ha), Panevėžys (474,520.40 ha), and Kaunas (450,355.52 ha) counties.

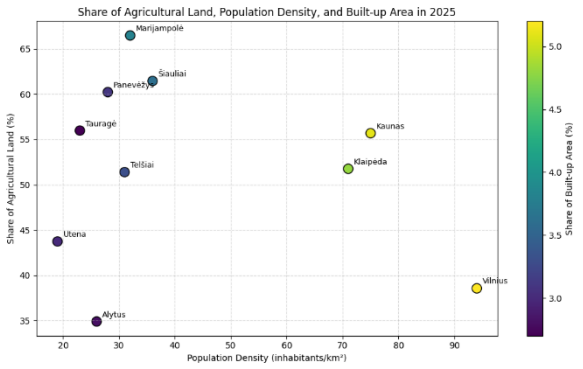
Although Vilnius County is the largest in terms of total area, it is characterized by a relatively low share of agricultural land (375,087.85 ha or 38.55%), reflecting the strong influence of urbanization and infrastructure development.

Marijampolė County stands out not only for having the highest proportion of agricultural land (66.49%), but also for its clear agrarian specialization within the national context.

Overall, in 2025, Lithuanian counties show clear differentiation in terms of agricultural land use intensity and landscape diversity. Central and northern Lithuania (Marijampolė, Šiauliai, and Panevėžys counties) is characterized by intensively agrarian landscapes, while southern and eastern Lithuania (Alytus, Utena, and Vilnius counties) exhibits a predominantly natural–urbanized landscape type. Kaunas, Tauragė, Klaipėda, and Telšiai counties occupy an intermediate position, with mixed landscapes reflecting a more balanced land-use structure.

To broaden the analysis, the interrelationships between agricultural land, urbanization, and population density in 2025 were examined. The typological analysis presented in Figure 1 reveals several important relationships between agricultural land share, population density, and the extent of urbanized areas. Intensively agrarian counties (Marijampolė, Šiauliai, and Panevėžys) are characterized by a high share of agricultural land (60.23–66.49%) and medium population density (approximately 28–61 inhabitants/km²). This indicates that agriculture dominates in these territories, while urbanization pressure remains relatively low.

In counties where agricultural land occupies a large proportion of the territory, the level of urbanization is generally lower. Šiauliai, Panevėžys, and Marijampolė counties contain some of the largest agricultural land areas (ranging from 296,902.01 ha to 524,731.29 ha), yet the share of built-up areas does not exceed 3.7%. This reflects the predominantly agrarian character of these regions and the limited intensity of urban development.



In counties with low population density – Utena (18.28 inhabitants/km²), Tauragė (22.15 inhabitants/km²), and Alytus (25.83 inhabitants/km²) – agricultural land areas in 2025 ranged from low to moderate (189,022.42 ha to 246,781.22 ha), while the share of urbanized areas remained small (approximately 2.7–3.1%). This suggests that low population density creates favorable conditions for more extensive land use and slower urbanization processes.

In 2025, agricultural land accounted for 38.55% of Vilnius County, which also recorded a high population density (95 inhabitants/km²) and the largest share of built-up areas among all ten counties (5.13%). These indicators point to strong urbanization pressure, suggesting that a portion of agricultural land may be converted into urbanized areas in the future.

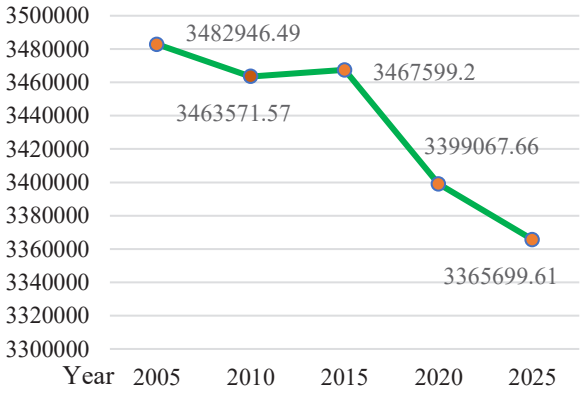
Overall, Figure 1 illustrates a clear negative relationship: as population density and the extent of built-up areas increase, the share of agricultural land decreases. Larger extents of built-up areas are concentrated in more urbanized counties, such as Vilnius and Kaunas, while smaller extents prevail mainly in agrarian regions.

Figure 1

The Interrelation of Agricultural Land, Urbanization, and Population Density in 2025

The analysis of agricultural land in 2025 shows that Lithuania's counties are clearly differentiated in terms of agrarian landscape intensity, urbanization pressure, and landscape heterogeneity. This assessment enables a systematic evaluation of the territorial agrarian structure and supports the planning of land-use policies that consider the interactions between urbanization and the natural environment.

Analysis of Changes in Agricultural Land in Lithuania, 2005–2025



Between 2005 and 2025, the area of agricultural land in Lithuania steadily declined. Nationally, agricultural land decreased from 3,482,946.49 ha in 2005 to 3,463,571.57 ha in 2010, corresponding to a reduction of 0.56%. In 2015, the area slightly increased to 3,467,599.2 ha, but it remained below 2005 level. By 2020, agricultural land had fallen to 3,399,067.66 ha, and in 2025 it reached 3,365,699.61 ha, approximately 0.98% less than in 2020. Over the entire 2005–2025 period, Lithuania's agricultural land declined by 117,246.88 ha, or 3.37%, Figure 2.

The analysis of agricultural land from 2005 to 2025 shows that its area decreased in all counties of the Republic of Lithuania, indicating a nationwide and persistent trend of agricultural land contraction over the past two decades. However, the magnitude of change varied considerably between counties, indicating strong spatial heterogeneity. These differences reflect varying intensities of urbanization pressure, demographic dynamics, and regional land-use policies.

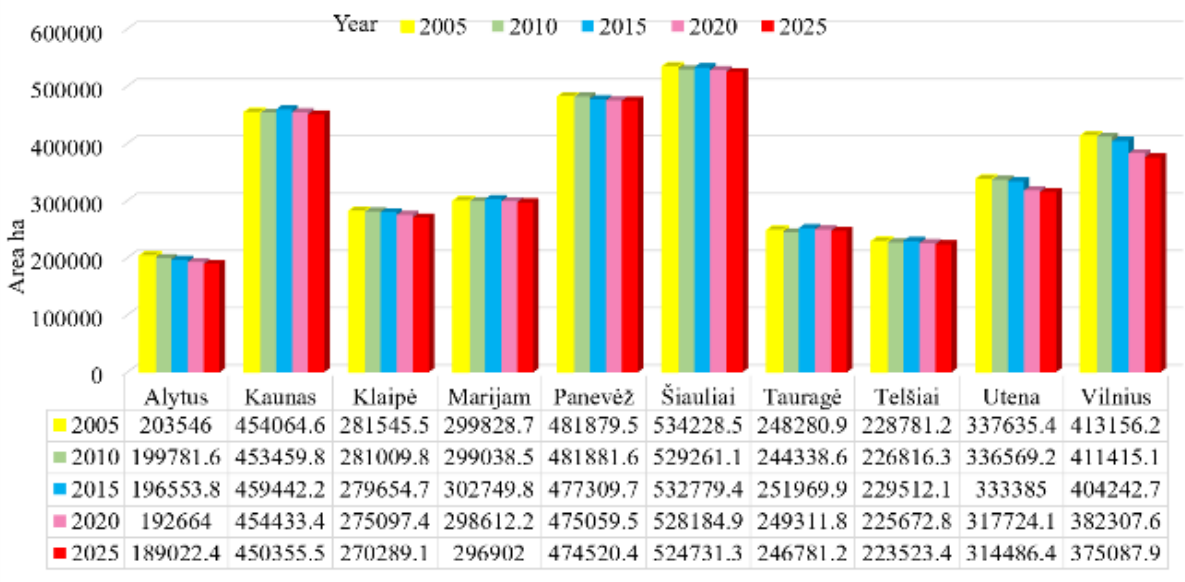
The results demonstrate that although agricultural land remains a dominant land-use category in Lithuania, its gradual decline and uneven spatial distribution indicate ongoing structural transformation of the national landscape system.

Figure 2

Changes in Agricultural Land Areas in Lithuania, 2005–2025 (ha)

Source: (Nacionalinė…, 2005–2025).

Between 2005 and 2025, the largest decreases in agricultural land were observed in Vilnius (38,068.39 ha or 9.22%), Utena (23,149.01 ha or 6.86%), and Alytus (14,523.58 ha or 7.14%) counties. The smallest percentage changes were recorded in Tauragė (0.60%) and Kaunas (0.82%) counties, Table 2.



According to data on changes in agricultural land from 2005 to 2025, Lithuanian counties can be divided into three main groups based on the scale and intensity of changes: rapidly decreasing agricultural land, moderate change, and relatively stable.

This regional typology allows for a systematic assessment of territorial differences and highlights the prevailing land-use processes.

The estimated average annual decrease in agricultural land, calculated as the total change between 2005 and 2025 divided by the 20-year period, was highest in Vilnius County, where approximately 1,903 ha per year were lost. This indicates a strong long-term tendency of agricultural land conversion driven by urbanization, suburban expansion, and infrastructure development.

Source: (Nacionaline…, 2005–2025).

In Utena county, the average annual decrease was about 1,157 ha, and in Alytus county about 726 ha per year, also indicating significant and long-term contraction of agricultural land.

Table 2

Changes in Agricultural Land Areas of Lithuanian Counties, 2005–2025 (ha and %)

Counties	Change ha	Change %
Alytus	–14,523.58	–7.14
Kaunas	–3,709.09	–0.82
Klaipėda	–11,256.39	–4.00
Marijampolė	–2,926.70	–0.98
Panevėžys	–7,359.05	–1.53
Šiauliai	–9,497.21	–1.78
Tauragė	–1,499.67	–0.60
Telšiai	– 257.84	–2.30
Utena	–23,149.01	–6.86
Vilnius	–38,068.39	–9.22

Moderate changes were recorded in Klaipėda, Šiauliai, and Panevėžys counties, where the annual decrease ranged from approximately 368 to 563 ha per year. In these counties, the decline in agricultural land was consistent but less intensive than in the eastern and southern regions of Lithuania. The changes occurred gradually, often integrating agricultural activities with other functions such as urban development, industrial expansion, or transport infrastructure.

Meanwhile, Kaunas, Marijampolė, Tauragė, and Telšiai counties showed the greatest structural stability. In Tauragė County, the average annual decrease was 75 ha; in Kaunas, 185 ha; and in Marijampolė, 146 ha per year. This indicates that the agricultural land structure in these territories remained relatively stable, with agriculture continuing to play an important role in the regional land-use system.

In summary, based on land-area dynamics, the counties can be clearly differentiated into structurally stable (Tauragė, Kaunas, Marijampolė, Telšiai) and high-change (Vilnius, Utena, Alytus) territories.

Causes of agricultural land decline in Lithuania and its Counties

The decline of agricultural land in Lithuania over the past 20 years is a complex process influenced by several interrelated factors, including urbanization and suburban expansion, changes in land use and infrastructure development, economic factors and decreasing agricultural intensity, natural and ecological factors, and regional characteristics (Antrop, 2004; Foley et al., 2025). These factors affect counties differently: in intensively agrarian counties, the reduction of agricultural land has been slower, whereas in urbanized or naturally constrained counties, the decline has been more rapid.

Urbanization in major cities and their surrounding areas alters land use, with portions of agricultural land being converted into residential, commercial, or industrial areas. This impact is most pronounced in Vilnius, Kaunas, and Klaipėda counties, where population density is rising and urban infrastructure is expanding.

In some counties, such as Alytus and Utena, agricultural land is decreasing due to conversion into forests, natural pastures, or protected areas. This process is linked to biodiversity conservation, environmental policies, and forest expansion programs.

Intensively agrarian counties, including Marijampolė, Šiauliai, and Panevėžys, retain a large share of agricultural land, although minor reductions are still observed due to infrastructure development and land consolidation.

Trends

Based on the above analysis, it can be predicted that in Vilnius, Utena, and Alytus counties – where the largest reductions in agricultural land were observed over the past 20 years – urbanization pressure and suburban expansion are likely to continue reducing agricultural areas. This is especially relevant for Vilnius county, where population density and the proportion of urbanized areas are the highest. Consequently, agricultural land is expected to continue declining in urbanized and environmentally constrained counties.

Kaunas, Marijampolė, Tauragė, and Telšiai counties maintained a relatively large area of agricultural land and structural stability during 2005–2025, indicating that agriculture will remain a dominant function in these territories. This suggests that these counties will continue to form intensive agrarian landscapes.

A second-degree polynomial trend model was applied to 2005–2025 time-series data in order to project agricultural land-use dynamics across Lithuanian counties for the period 2030–2040, Table 3. The results indicate a non-linear and spatially heterogeneous decline in agricultural land, with an overall tendency toward accelerated reduction in more urbanized and economically dynamic regions.

In 2030, the largest agricultural land areas are projected in Šiauliai, Panevėžys, and Kaunas counties, reflecting their historically strong agricultural structure. However, even in these regions a gradual decline is evident. More pronounced reductions are observed in Vilnius, Klaipėda, and Utena counties, where land-use conversion processes are more intensive due to urban expansion, infrastructure development, and peri-urban land fragmentation.

By 2035 and especially by 2040, the polynomial model suggests a strengthening of the downward trend, with differences between counties becoming more pronounced. Vilnius County demonstrates the most substantial relative decrease, indicating strong pressure from urbanization and land conversion to non-agricultural uses. Similar, though slightly less intensive, patterns are observed in Klaipėda, Utena, and Tauragė counties. In contrast, Kaunas and Panevėžys counties exhibit a more gradual and stable decline, suggesting a comparatively slower pace of land-use transformation.

Table 3

Polynomial forecasting of agricultural land-use dynamics in Lithuania (ha)

County	2030	2035	2040
Alytus	185,256	181,431	177,547
Kaunas	443,449	433,836	421,660
Klaipėda	266,182	255,848	243,739
Marijampolė	292,139	285,507	276,991
Panevėžys	472,401	469,389	465,351
Šiauliai	513,064	502,702	490,504
Tauragė	241,621	235,373	227,801
Telšiai	219,343	214,254	208,345
Utena	296 610	282,890	267,311
Vilnius	352,809	329,424	302,366
Lithuania	3,295,805	3,215,633	3,121,096

At the national level, total agricultural land is projected to decrease from approximately 3.30 million ha in 2030 to about 3.12 million ha in 2040. This corresponds to a reduction of roughly 5–7% over the 10-year period, with a clear indication that the decline is not linear but accelerates over time.

Agricultural land dynamics in Lithuania generally follow the declining trend observed across the European Union; however, the scale, spatial differentiation, and underlying drivers of change are notably distinct. While agricultural land in the EU is projected to decrease modestly (approximately 1–2% per decade) (European Commission, 2021), the results of this study indicate a substantially steeper decline in Lithuania, reaching about 5–7% over the period 2030–2040. Moreover, land-use change in Lithuania is characterized by pronounced intra-national variability. In contrast, agricultural land change across Europe tends to exhibit broader regional patterns with comparatively lower internal disparities (Eurostat, 2023). The identified non-linear (polynomial) trajectory of agricultural land change in Lithuania further suggests a transitional land-use system shaped by post-socialist restructuring, demographic shifts, and uneven economic development, consistent with patterns observed in Central and Eastern Europe (Joint Research Centre, 2019). Conversely, most EU countries demonstrate more stable and gradually evolving land-use patterns, largely regulated by policy frameworks and environmental constraints (European Environment Agency, 2020). Overall, these findings indicate that Lithuania represents a more dynamic and spatially heterogeneous system of agricultural land transformation, whereas the European context reflects a relatively mature and stabilized land-use regime.

Conclusions

1. In 2025, Lithuania's agricultural land covered 51.55% of the country's territory, indicating that more than half of Lithuania's area is used for agricultural activities. The highest proportion of agricultural land was recorded in Marijampolė (66.49%), Šiauliai (61.46%), and Panevėžys (60.23%) counties, while the lowest was in Alytus (34.89%), Vilnius (38.55%), and Utena (43.73%) counties.
2. Between 2005 and 2025, Lithuania's agricultural land decreased by 117,246.88 ha, or 3.37%.
Agricultural land decreased in all counties, with the largest reductions in Vilnius (9.22%), Utena (6.86%), and Alytus (7.14%) counties. The smallest percentage changes were recorded in Tauragė (0.60%) and Kaunas (0.82%) counties.
3. Based on agricultural land dynamics, Lithuanian counties can be clearly divided into structurally stable (Tauragė, Kaunas, Marijampolė, Telšiai) and high-structural-change territories (Vilnius, Utena, Alytus). This differentiation reflects the uneven impact of urbanization, demographic processes, and land-use transformations across the counties.
4. The reduction of agricultural land in Lithuania over the last two decades is a multifaceted process driven by a combination of interconnected factors, such as urban and suburban growth, shifts in land use and infrastructure development, economic influences, ecological and natural conditions, as well as regional-specific features.
5. According to the polynomial projection, national agricultural land is expected to decrease from about 3.30 million ha in 2030 to 3.12 million ha in 2040 (−174,000 ha; ~5–7%). The largest losses are projected in Vilnius (−50,443 ha), followed by Utena (−29,299 ha) and Klaipėda (−22,443 ha), reflecting strong urbanization pressure. Smaller decreases are observed in Kaunas (−21,789 ha), Šiauliai (−22,560 ha), and Panevėžys (−7,050 ha), indicating relatively higher landscape stability.

GREENHOUSE GAS EMISSION REDUCTION POTENTIAL ASSESSMENT FROM LAND-USE CHANGE IN AGRICULTURE

***Kristiāna Griķe[1], Raimonds Kasparinskis[1,2]**

Abstract
This study analyses the potential greenhouse gas emission reduction of land-use change interventions in agricultural land with organic soil in the district of Kuldiga, Latvia. Using the Land-use and Land-use Change and Forestry (LULUCF) decision-making support tool, three nature-based interventions were selected: agricultural land afforestation with native tree species, with monoculture of fast-growing tree species, and natural wetland forest ecosystem conversion to agricultural land. A dataset of 152 valid entries was created to analyze intervention combinations across three factors: location, agricultural use and field management. Each entry estimates the potential emission reductions that a specific combination would contribute. Non-parametric statistical methods (Kruskal-Wallis and Dunn test) were applied to determine the most influential factors of intervention efficiency, and Gamma generalized linear model was used as a basis for the prediction proposal. Results indicate that afforestation with fast-growing species offers the highest median emission reduction potential (607 t $CO_{2\text{-eq}}$ ha^{-1}), significantly exceeding other interventions. However, the most influential factor is the agricultural land-use with 26.2% effect size and landscape characteristics with 15.4%, leaving the intervention itself only the third factor in terms of greenhouse gas saving. Grasslands exhibit the highest potential across all scenarios, while field management has no significant effect. The LULUCF decision-making support tool is ideal for preliminary site selection for nature-based climate mitigation interventions, but a combination with actual land-use and baseline emission amounts would improve the user experience and strengthen spatial planning in rural areas.
Keywords: organic soil, afforestation, climate neutrality, decision support tool, spatial planning.

Introduction

Growing concern about climate adaptation and mitigation has been reflected throughout European, national, and municipal-level planning documents. As the Sustainable Energy and Climate Adaptation plan for Kuldiga district 2021 – 2030 is entering its second half, a clear path forward for the climate adaptation sector has yet to be defined. Nature-based solutions are considered essential for land-use management due to the soil potential as a carbon sink. Regarding the climate, there are dual expectations of soil: to capture and store as much carbon as possible, and to remain healthy and capable of producing food and timber yields by maintaining its structural stability and erosion resilience. Recommendations for achieving the planned emission reduction of 6 Gt CO_2 ha^{-1} across agricultural and land-use change sectors, with a focus on afforestation of organic soils (EU Strategy for Adaptation to Climate Change, 2021; National Energy and Climate Plan of Latvia, 2021; Lazdiņš, 2023; Kuldīgas novada pašvaldība, 2021).

The largest potential greenhouse gas (GHG) emission reduction potential in agricultural lands in Latvia is afforestation and agroforestry (Licite, 2024). Especially in organic soils, as they are said to contribute 3.1 million tonnes of GHG emission to the atmosphere (Lazdiņš et al., 2023). Afforestation as a carbon dioxide removal strategy and sustainable agriculture are recognized as two effective tools for increasing carbon *sinks* (MéNard et al., 2023). A set measurement of CO_2 equivalent is used when assessing climate adaptation and mitigation, including the land-use and land-use change contribution to the emission amount (Calvin et al., 2023). The focus of this article is nature-based mitigation that narrows down to carbon flux between the atmosphere, soil and biomass, while the information available as well as the measurements used in the literature and decision support tool is CO_2 equivalent of greenhouse gases (GHG).

Nature-based solutions have been implemented and studied in other European countries, showing the emission reduction effect. It is important to emphasize that the carbon sink consists of soil and biomass growing from it. Depending on the land-use type, a larger part of stored carbon can be either soil or biomass, and it can transfer during the aging process of a forest stand. Despite the rapid carbon intake and GHG retention during the initial phase of afforestation (Baumgarten et al., 2021; Pilli et al., 2016), it does not always result in net ecological carbon gains during a decadal timespan (Strand et al., 2020). For example, early age Scots pine (*Pinus sylvestris*) stand in Latvia absorbs 0.69 t C ha^{-1} in biomass and deposits soil organic carbon by 0.08 ± 0.33 t C ha^{-1} in the 0-40 cm soil layer during one year, and a juvenile Norway spruce (*Picea abies*) stand absorbs 1.05 ± 0.23 t C ha^{-1} in biomass, while soil organic carbon is reduced by 0.54 ± 0.16 t C ha^{-1}, and biomass carbon increase in Silver birch (*Betula pendula*) stand is 1.05 ± 0.23 t C ha^{-1} with a SOC extraction 0.66 ± 0.15 t C ha^{-1} (Petaja et al., 2023). The full life span of a spruce stand can offer a 1600 t C ha^{-1} accumulation during 120 year period, without mentioning of the amount stored in soil (Lazdiņš, 2023). Researchers in the United Kingdom discovered that the conversion of meadow into a forest caused a reduction in soil organic carbon. Functional shift of mycorrhizal community connected with the tree roots causes nutrient mining, where trees allocate their photosynthetic carbon into roots. It stimulates microbial growth, and by increased respiration, also increases carbon release into the atmosphere (Friggens et al., 2020).

While afforestation offers an immediate effect on climate mitigation, it does compete with agricultural land-use for food production. This leads to a careful site selection requirement for both climate farming and food production, and local criteria are needed for sustainable spatial planning in rural areas.

Since an empirical observation of all the carbon and greenhouse gas flux is too expensive, a mathematical approximation model has been developed – the Land-use and Land-use Change and Forestry (LULUCF) decision support tool. It combines 17 interventions, of which 9 consider forestry and 8 agricultural, and gives a calculated amount of GHG emission reduction in case an intervention would be implemented, together with a territory suitable for it (Nipers, 2025).

The main question that drives this research is which land-based parameters prove to be the most influential for the emission reduction in land-use change sector. What conclusions can this tool offer in order to enhance data-based decision-making process for nature-based solutions for climate mitigation in Kuldiga district?

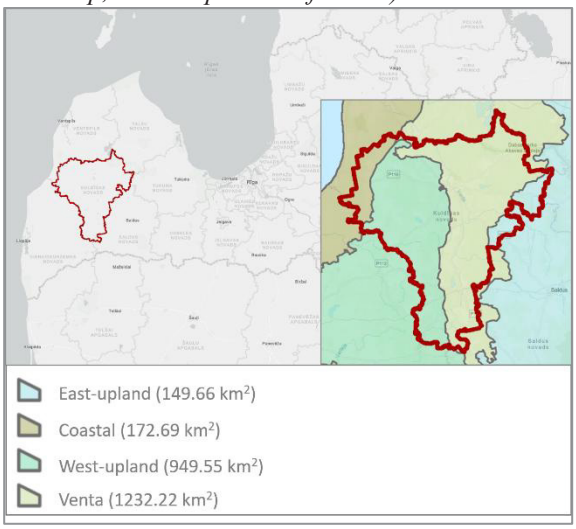
Materials and Methods

Land-Use, Land-Use Change and Forestry (LULUCF) decision Support Tool provides potential greenhouse gas flux calculations for a collection of 17 nature-based interventions: 9 forestry and 8 agricultural land-use change. Chosen for data analysis are the following three: 1) Afforestation of agricultural land on organic soils (AGRI-FOR), 2) Restoration of natural, waterlogged forest ecosystems on organic soils in agricultural lands (FOR-AGRI), 3) Monoculture plantations of fast-growing tree species on agricultural land as an alternative to afforestation with native tree species (AGRI-MONOFOR). This selection of nature-based interventions comprises an ongoing process of rural depopulation and afforestation due to natural succession (Vinogradovs et al., 2017), which is considered a negative side effect, overtaking possibly productive territories. Therefore, a prognosis on climate mitigation effect and the most suitable implementation territories for intentional afforestation with either native or fast-growing tree species can lead to possible solutions for a site-specific and more valuable land-use. Intervention of returning wet natural forest ecosystems into agricultural land mainly is a comparison, as well as a long-term speculation, in case local food production in the future could be limited due to vast forested territories.

After an intervention is chosen, the Tool provides seven filters from which five are used as qualitative factors in an ordinal scale to determine their effect on the potential GHG emission reduction results in case they were implemented. The district of Kuldiga municipality is the experimental area. Intervention itself is the first factor, as its effect and dependence from other factors is the focus of this research. Landscape is the factor as there are four different landscape zones within the district of Kuldiga, and they differ by terrain genesis, main deposit mineral that is also soil parent material, and main land-use, as well as by their size. Agricultural management system is the third factor – either conventional (includes intensive crop production, mechanization, mineral fertilizer and chemical pesticide use, focus on productivity) or organic (extensive production that values natural processes, natural fertilizer and no chemical pesticide use, focused on soil protection). The size of a single field is the fourth factor (<20 ha or 20 – 100 ha). As the fifth factor, a filter is selected for agricultural use – Grains, oil seeds and legumes (as the widest use of arable land), Temporary cultivated grassland (mixture of grasses, forages including protein crops sown in arable land and declared for less than five consecutive years), Fallow land (green manure) and Other crops (all other agricultural production that is not vegetables, orchards and none of the abovementioned sown pure in arable land). Filters of land-use restriction and land quality based on potential productivity are not considered in this analysis.

Landscape zones (Figure 1) within the Kuldiga district are:

1) The East Kurland upland (East-up) – a slightly wavy terrain of moraine with arable land in the highest parts, and grasslands, pastures and meadows in the lowest parts, with tree and shrub intersections. Several hills in this landscape are covered with forest (mostly pine and birch with large areas of black alder tree stands – species not specified). Soil parent material is formed by various proportions of clay and sand, lowest parts of the terrain hold peat deposits. The eastern part of this landscape's agricultural land tends to overgrow with trees and shrubs.



2) The West Kurland upland (West-up) – a flat, slightly wavy terrain of glaciofluvial and glacigenic deposits. Forest areas are fragmented, scattered patches of drained agricultural land are located on the highest places of this landscape zone. High heterogeneity of soil types, moisture, microclimate, and vegetation.

3) The Baltic sea coastal and former coastline area of different Baltic sea development stages (Coastal) – soil parent material is formed by Littorina sea sands and Baltic Ice lake sandy sediments. Intensive forestry is the predominant land-use with unspecified pine, spruce, and birch species stands of various ages, afforested both intentionally and naturally. Small rivers are often straightened for the drainage of valleys that are used in agriculture as pastures and grasslands. Besides the intensive forestry and extensive agriculture, an active process of land abandonment and afforestation by natural succession takes place.

4) The Venta River Valley (Venta) – sits on Baltic Ice lake sandy sediments and a glaciolacustrine plain, with occasional aeolian dunes and glacigenic tills. Main land-uses are agriculture on drained soils (intensive and extensive) and forestry (with spruce, birch, pine, distinct places with oak and ash tree dominance). Much of this landscape is of aesthetic quality, where intentional afforestation is not recommended in several

places due to scenic open views. Rivers are meandering through dolomite and often create deep valleys in the upper sediments, resulting in biodiversity hubs and tourist attractions. Landscape is a mosaic with high sensitivity to land-use change (Nikodemus et al., 2025).

Figure 1
Kuldiga district and Landscape zones (ArcGIS Online base map, Landscape atlas of Latvia)

Above-mentioned agricultural land-uses were chosen due to their abundance in results extracted in the Tool, while the 'vegetables', 'potatoes', and 'orchards' for the selected interventions showed no suitable territories for the selected interventions within the district of Kuldiga. The type of agricultural use can indicate the already existing GHG emission variability. Three interventions filtered by four landscape zones, two management types, two field size groups and four types of agricultural use either before afforestation or after deforestation with which the emission difference is set, together make a 192 sample size database, including a range of 64 digits per intervention, 48 per each landscape zone and agricultural use types. Several filter combinations yielded null results, meaning no applicable territory was found, because each intervention requires organic soil by default (Nipers, 2025). For example, AGRI-FOR intervention for organic management type on field size 20-100 ha has results for such agricultural uses as Grains, oils and legumes, and Fallow land on organic soil, while Grassland and Other are not agricultural land-use types on organic soils within the landscape of East Kurland upland; therefore, the conversion from agricultural to forestry land-use on organic soils does not apply and creates a null data entry. Most of the null values are for organically managed fields of 20-100 ha, indicating that existing agricultural use of organic soils dominate in smaller fields. Valid results remained in 152 rows and altered the initial set of data into an unbalanced design database, which is considered for the selection of data analysis methods.

D*ata analysis*. After selecting each intervention and rendering every filter combination, the GHG emission reduction value and suitable area for the respective combination are collected into a database for further analysis in *RStudio.* Skewness of the preliminary scatter plot declines the hypothesis of normal distribution. Statistical analysis begins with the impact assessment of each factor (intervention, landscape, management type, field size, and agricultural use) on the possible emission reduction by using the *Kruskal-Wallis* test. Factors with significant impact on emission values are selected for further analysis for the calculation of inner rank differences with the post-hoc pairwise comparisons *Dunn* test. For example, not only can we know that agricultural use has a significant effect on emission reduction by the land-use change, but also that temporary cultivated grassland exceeds all of the other agricultural use types. Detecting factors with significant impact on the GHG reduction potential, as well as knowing the inner group differences, a prediction for the most effective intervention, location and management combination can be clarified. In order to create a prediction, the Generalized linear model (GLM) with Gamma error distribution and logarithmic function is used to reveal the combined effect of the most influential factors. From these results, an estimated marginal means prediction heatmap is created to visualize potential GHG emission reduction for each combination.

Results and Discussion

The primary descriptive results delineate the intervention of afforestation on agricultural land with organic soils as the most effective, with median values of 607.0 t $CO_{2\text{-eq}}$ ha^{-1} potential reduction by using monoculture fast-growing tree species, and 319.5 t $CO_{2\text{-eq}}$ ha^{-1} with native species, while the reverse intervention of turning a natural wetland forest ecosystem into agricultural land-use can offer an emission reduction potential of 132.0 t $CO_{2\ eq}$ ha^{-1} (Table 1).

In terms of landscape zone, the West Kurland upland and the Venta Valley dominate the factorial impact by their similar median values (578.5 and 577.0 t $CO_{2\ eq}$ ha^{-1}). The maximum potential emission reduction possible in the West Kurland upland shows 9,596 t $CO_{2\ eq}$ ha^{-1} and the Venta Valley – 5,995.0 t $CO_{2\ eq}$ ha^{-1}. Interestingly, the very small Coastal landscape zone equals the Venta River valley by its maximum values and sums, while the median is nearly eight times smaller. The data variability with few high-value entries indicates the possibility that Coastal landscape holds more organic soil areas that are currently in agricultural use.

Land-use conversion to and from the four types of agricultural uses distinguishes Grasslands, with the highest minimal value achievable in the case of afforestation intervention, as well as the total sum and median. The only exception is the maximum value (that is second to Grains, oils and legumes).

Interestingly, the same value of 9,596.0 t $CO_{2\ eq}$ ha^{-1} occurs in all factors, leading to a thought that it is one filter combination selected in the decision-making tool. It illustrates the potential GHG emission reductions if the AGRI-MONOFOR intervention - afforestation of fast-growing monoculture tree species on arable land – were applied to conventionally managed grains, oilseeds, and legumes in fields up to 20 ha. Total area suitable for this exact factor combination is 799.7 ha. In other landscapes, this combination would be suitable for 35 ha in East-upland, 115 ha in the Venta Valley, and 6 ha in Coastal landscape zones.

Table 1
Total greenhouse gas emission reduction potential by the factor

	Other[a]	2.0	1,826.0	7,613.0	81.0	

**P-value total* indicates the factorial impact on emission reduction potential. Different superscript letters distinguish significant inner variability of the ordinal groups within each factor.
***A conventional management system is productivity-based and includes the use of mineral fertilizers and chemical pesticides. An organic management focuses on soil health, uses natural fertilizers, and does not use chemical pesticides.

The factors of Intervention, Landscape and Agricultural use have a significant impact on the emission reduction potential, and ordinal groups within these factors show significant differences within factors, but there must be selective combinations more effective than others that the Decision-making tool is not able to filter out.

Land-use change into a forest has a potential emission reduction range of 2.2 –13.3 t CO_2 eq ha^{-1} (Lazdiņš, 2023; Strauss et al., 2024), but the carbon sink tends to slow down after 10 – 15 years (Black et al., 2025). Vast differences between our results in potential emission reduction differ from the ones stated in the literature, possibly because the values extracted from the Tool are mathematically calculated instead of the actual measurements taken from the above-mentioned sources. Also, precise soil properties and tree species are not defined and may cause the gap.

The effect size percentage for both GHG and suitable area, and total corresponding area for each factor, is shown in Table 2. Agricultural use has the largest effect and determines 26.2 % of the emission reduction potential as well as the total suitable area. The other large effect size is created by the Landscape zone – 15.4%.

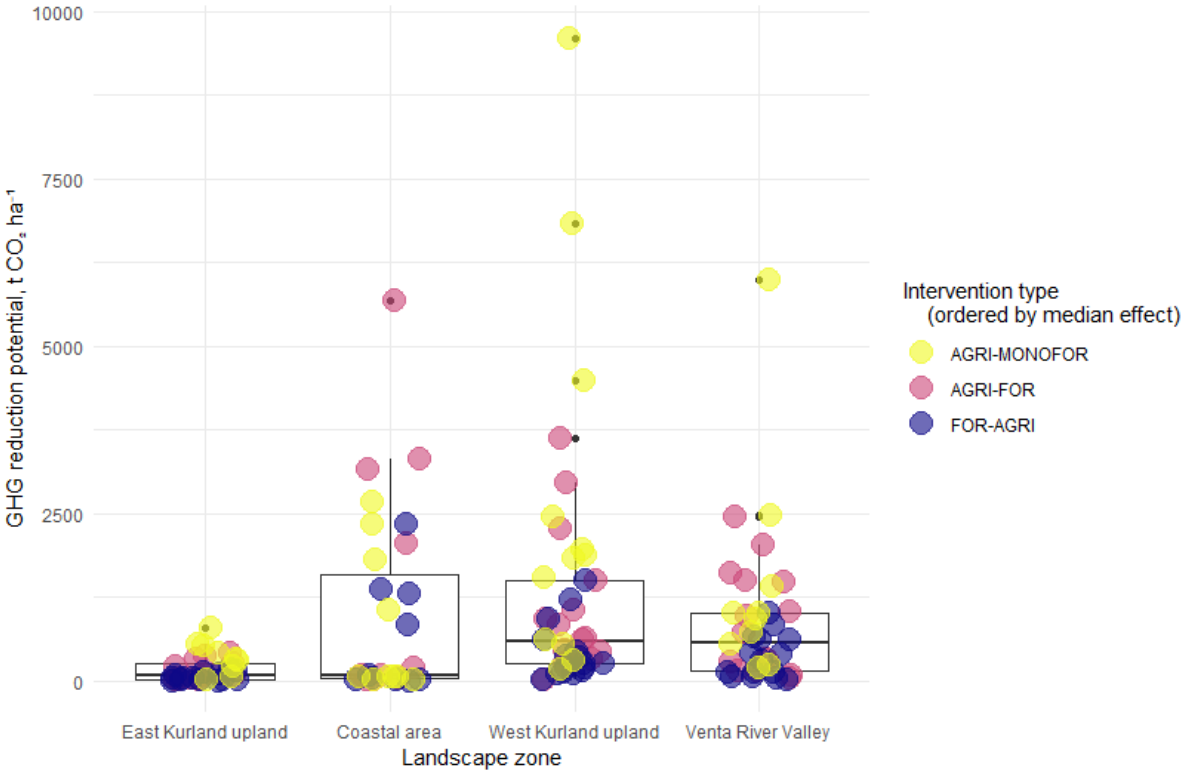

Table 2
Factorial effect size for GHG reduction potential and total corresponding area

Factor	GHG red, %	Total area, %
Agricultural use	26.2	28.0
Landscape	15.4	16.5
Intervention	7.4	0.9
Field size	0.5	0.3
Management	0.2	0.2

The management system and field size do not create a significant impact on the potential GHG reduction amount and show no factorial effect size; therefore, they are excluded from further analysis. Researchers in Lithuania have discovered that the variation component of soil type is 29.5%, and land-use contributes 45.9% (Muraškienė et al., 2023) to the

emission reduction effect.
Secondary analysis is the visual assessment of the factorial impact on potential emission reduction based on landscape and agricultural use (Figure 2 and 3).
A narrow distribution of potential values is in the East Kurland upland, with each filter combination resulting in less than one thousand tonnes of carbon equivalent reduction per hectare. Regardless of its size being similar to the East-upland landscape, the range resembles the district's largest Venta Valley landscape, which is seven times larger. It is also the only landscape in which afforestation with native tree species (AGRI-FOR) dominates the highest potential values, and not the intervention of monoculture fast-growing tree species. It stands out with high potential GHG savings from natural wetland forest ecosystem conversion into agricultural land-use (FOR-AGRI).

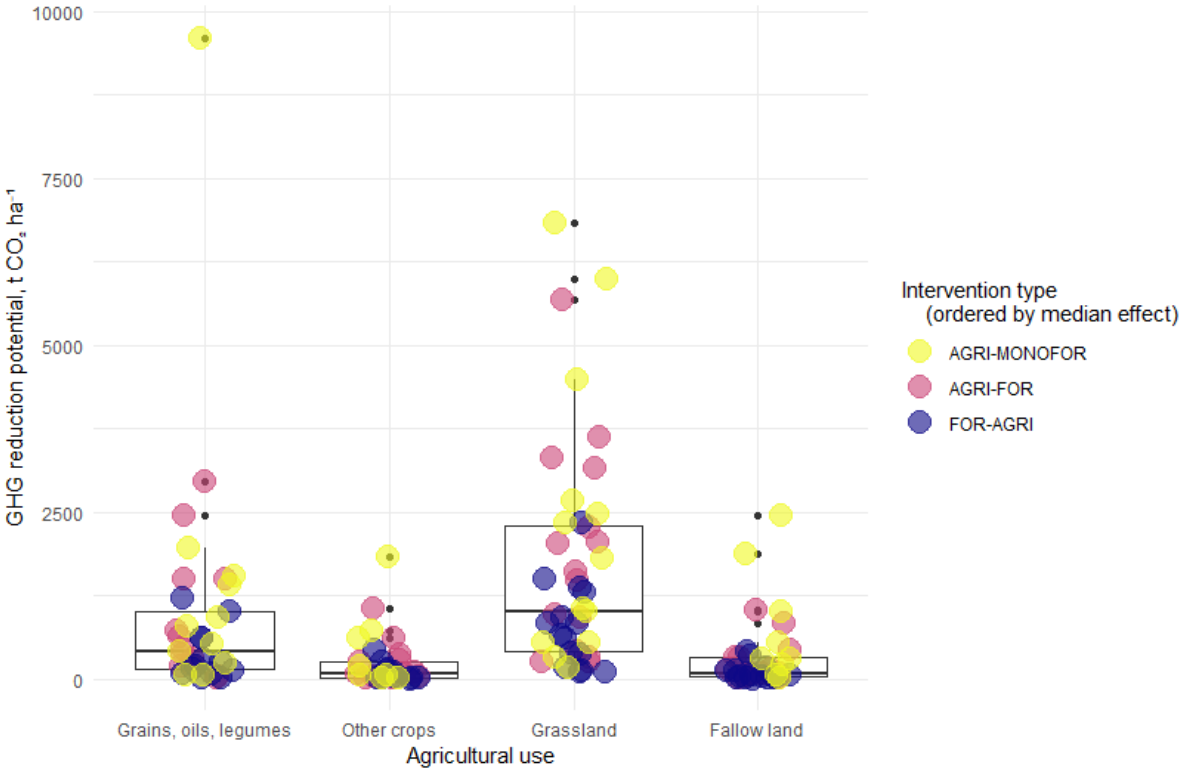

Figure 2
GHG emission reduction potential by intervention and landscape

The West Kurland upland and the Venta Valley exhibit the highest potential values from afforestation with fast-growing tree species (AGRI-MONOFOR) The third intervention of natural wetland forest ecosystem conversion into agricultural land-use (FOR-AGRI) shows comparatively low emission reduction potential, except for the Coastal landscape, in which it even exceeds some agricultural land conversion to a forest.
Regarding the similarities between the Coastal and Venta valley landscapes, the visualization in Figure 2 confirms the extensive distribution of extreme values in the Coastal landscape. In terms of maximum and cumulative values, the potential GHG reduction varies widely between regions; the median value is 74 t $CO_{2\,eq}$ ha^{-1}, for the Coastal landscape to 577 t $CO_{2\,eq}$ ha^{-1} for the Venta Valley The only outlier in Venta cluster is Grassland on field size <20 ha for the AGRI-MONOFOR intervention, and it is suitable for 499 ha. Comparing these results with the Landscape plan of Kuldiga, Coastal landscape is already predominantly used for intensive forestry and has a fragmented character. Exceptions are two small river valleys that are historically used as meadows and pastures, and their preservation is a recommended quality goal where afforestation would disrupt the biologically valuable grasslands. This landscape offers exceptional potential in natural wetland forest ecosystem conversion into agricultural land, especially to Grassland and still contribute to climate mitigation. The decision-making process for the afforestation licensing that determines if it coincides with the municipal spatial plan, should include the scenic value of the landscape into consideration in order to balance out the climate, biodiversity, and scenic objectives. The West Kurland upland is described as a typical agricultural landscape on drained land and well-cultivated soils that are still actively used for production, including intensive forest areas. Abandonment and natural afforestation take place, but scarcely.
The Venta River Valley is actively used for agriculture and forestry, while recreation and nature tourism are also major activities. These two largest landscapes are

mosaic and evaluated as distinctly aesthetic.
Both hold widespread visual and culturally historic values, and are intertwined with high aesthetic value roads. To maintain the landscape quality goal and climate mitigation balance, it would require careful site selection for afforestation interventions where distinct views are not closed. The East Kurland upland is small by area and its low-value emission reductions are formed by small-scale areas, yet it can be considered for climate mitigation interventions as long as the mosaic character is retained (Nikodemus et al., 2025).

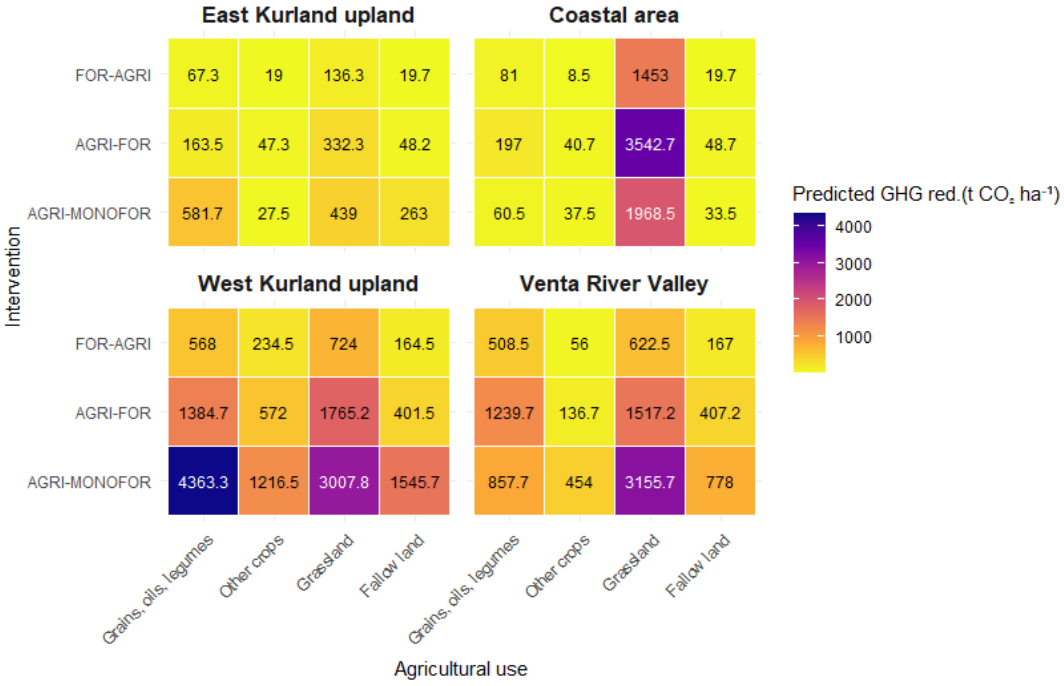

Figure 3
GHG emission reduction potential by intervention and agricultural use

The type of agricultural use impact on intervention effect is visualized in Figure 3. The highest average values can be achieved in Grassland agricultural land-use. Fallow land and Other crops offer similarly low emission amounts; therefore, the emission reduction potential is slight.
Previous agricultural use is considered a strong influential factor also in other research, especially for maintaining soil organic carbon (SOC) – grassland tends to accumulate, and arable land releases carbon through mechanical disturbance. Even the plant variety in grasslands can determine the amount of SOC – mixed plant composition show 10.7% higher amount of SOC than in monocultures (Wang et al., 2020). In an experimental pasture afforestation in Norway, soil organic carbon transfers from soil to biomass in the early years of the tree stand. Both these land-uses have a significant impact on bulk density that changes the soil carbon content in various depths (Strand et al., 2020). Carbon stock transfers from the upper soil horizon to the tree biomass and begins leaching into deeper horizons due to acidification. Carbon removal from the atmosphere is not necessarily an addition to the total ecological carbon after the tree stand is utilized (Friggens et al., 2020; Pilli et al., 2016).
Research from Spain states the opposite, that the labile carbon from the litter layer is also incorporated within soil mineral layers after the land-use change. Higher carbon content in soil was in a floodplain site on humic fluvisol, and its previous land-use was a grassland with no change of SOC after the afforestation. In the second experimental site, which was a maize crop arable land-use, afforestation added carbon to the soil (Priano et al., 2023) although Kravchenko & Roberts (2017) emphasize that only a whole soil profile analysis can ensure the carbon dislocation and transformation within soil.
The focus at hand is the nature-based climate mitigation. By recognizing the potential side-effects of greenhouse gas reduction interventions, the rural spatial planning process should simultaneously aim to achieve climate neutrality, protect biodiversity, and preserve soil health and landscape quality. Therefore, an easily understandable prognosis is needed. The cumulative effect of agricultural use and landscape can be taken into account before suggesting, supporting or stimulating land-use change, especially afforestation of agricultural land. A prediction based on Gamma Generalized Linear Model is visualized in Figure 4.
All three factors influence the potential GHG emission

amount significantly when analysed separately, but the model highlights that 31% of the outcome is influenced by the agricultural use and 25% by the landscape area. Landscape and agricultural use have a very strong factorial interaction and together determine 56% of GHG emission reduction potential (<0.001), but the model shows no significant interaction between intervention and agricultural use.
Grassland is the dominating agricultural land-use type across all interventions, stating also that it is already the most common agricultural use on organic soil. Afforestation with a monoculture of fast-growing tree species in European experience with using afforestation as a climate mitigation tool has shown that it works as a carbon farming, while the natural quality of the ecosystem may be compromised (Hamidov et al., 2018; Jost et al., 2021). General caution is recommended in choosing areas for afforestation interventions, so that climate incentives do not compete with other environmental goals or food security (Hua et al., 2025). Often, carbon exchange and pricing are mentioned, but soil recovery costs after carbon depletion, acidification, and bulk density reduction are not.

Figure 4
Predicted GHG emission reduction by landscape and intervention, t CO_2 ha^{-1}

In the prognosis heatmap, the highest possible emission savings can be expected from the fast-growing monoculture forest intervention (AGRI-MONOFOR). In the West-upland landscape, the largest saving of 4,363.3 t $CO_{2\ eq}$ ha^{-1} are predicted for the afforestation of Grain, oil seed and legume arable land. Meanwhile, in the Venta River Valley an emission reduction of 3,155.7 t $CO_{2\ eq}$ ha^{-1} is predicted from afforesting Grassland. Coastal area potential of the highest emission reduction of 3,542.7 t $CO_{2\ eq}$ ha^{-1} can be achieved not by fast-growing tree species afforestation, but from native species forest on Grassland agricultural land-use.
The East Kurland upland is the least effective landscape for any of the interventions and can be left out of large-scale carbon farming driven afforestation. The West-upland and Venta landscapes are the largest ones; therefore, they show the most potential for emission reduction interventions. Meanwhile, these territories are also valuable for food production, their ecological importance and recreational function.

These findings coincide with other research and show that land-use is the dominant factor determining carbon sink. Grassland conversion into arable land creates the largest depletion of SOC in comparison with arable land converted into grassland or forest and grassland to forest (Jost et al., 2021; Muraškiene et al., 2023; Priano et al., 2023). Afforestation can cause SOC depletion as it transfers to biomass, leaving the soil with reduced amount of organic carbon, that is extracted, leached, mineralized or lost due to soil respiration, and the most vulnerable are grasslands (Friggens et al., 2020; Strand et al., 2020). Crop rotation, drainage, change of arable land into grassland and vice versa are established as effective climate adaptation interventions that reduce soil threats and improve soil functions (Hamidov et al., 2018).
One threat that afforestation can counteract is soil compaction, as root system development significantly reduces bulk density (Hamidov et al., 2018). Consequently, this intervention is highly suitable for areas of moderate productivity, provided tree species

are selected that do not cause soil acidification. Even the below-ground habitats are damaged in site preparation phase for afforestation, a new ecosystem will evolve over time. Therefore, intervention of agricultural land afforestation with native tree species in small-scale is advisable in mosaic landscapes with high biodiversity.

Even though afforestation may not always be the most sustainable land-use change in terms of food security and soil health, it could add value to abandoned agriculture lands where natural succession has begun to take place (Thibault et al., 2022).

Research done in Austria used three land-use intensities: land spearing – where productive and nature protection areas are separated, land sharing – agricultural and biodiversity share the same landscape, and balanced land-use – a combination of spearing and sharing. These land-use intensities, together with climate change scenarios, were modelled to estimate soil characteristics, including soil organic carbon sink in three different land-use change experiments between arable, grassland, and forest. A combination of land-use and climate change scenarios proved that land sparing is the most vulnerable and contributes the least to carbon sink capacity due to its intensive arable use. Their finding strengthens this research by stating that mosaic and mixed-use landscapes can be 'carbon-neutral enough' with soil cultivation and agronomic methods, while large arable territories can be considered for use in carbon farming. Areas with organic soils, situated in flat, homogeneous landscapes with arable land-use and already depleted biodiversity, are well-suited for intentional afforestation - even with the fast-growing tree species. Leaving more diverse areas for medium and small-scale food production, landscape, soil health and biodiversity preservation (Jost et al., 2021).

Irish researchers, who tested Canadian land-use models for forest and agricultural areas, discovered that empirical field sampling provides lower emission and sequestration values than the satellite-image and carbon estimation of the model (Ituen & Hu, 2024). This is supported by Kravchenko and Robertson (2010) who proved that a whole soil profile analysis can reveal contradicting carbon cycle processes.

Identifying the largest uncertainty elements of an emission estimation model is suggested by McGlynn and her research team (McGlynn et al., 2022), possibly narrowing down the supplementary data needed for decision-making. Uncertainty discovered in this research is yet an unknown quantitative balance between landscape quality, soil health, and long-term soil organic carbon deposit, as well as food production. The cumulative effect of these territorial qualities ought to be evaluated equally within the decision-making process. As the research team of MéNard (2023) suggests, an analytical framework is needed and coincides with the results of this research. The intervention itself is only the third in its effect size for emission reduction impact, and an analytical framework would best work when used together with soil data, forest stand placement and development phase, as well as with the agricultural use and landscape. A qualitative and balanced approach is recommended for the Sustainable Energy and Climate Adaptation plan of Kuldiga district.

The carbon flux is not continuously observable, thus, not entirely reliable. Model deviation can be up to 10% (MéNard et al., 2023), signifying that it is most useful for preliminary analysis in site selection for climate mitigation interventions. Since the LULUCF Decision-making support tool offers a mathematical calculation for possible emission reduction and not the actual amount of real-time GHG flux, a direct connection with agricultural use and afforestation activities is advisable. Additional data of soil type and land-use are welcome to secure the calculation. Further research in soil profile analysis according to the intervention and agricultural use combination could solidify the prediction model and support the decision-making process at municipality level.

Conclusions

1. Monoculture forests with fast-growing tree species can offer the largest greenhouse gas sequestration, compared to other intervention types.
2. The majority of the potential emission reduction potential derives from low-effect applications.
3. The largest effect size on GHG sequestration from land-use change is created by agricultural use to or from the conversion is implemented, exceeding the effect size of the intervention itself.
4. The LULUCF tool offers estimation of potential emission change provided by land-use change, ideal for preliminary site selection.
5. Soil analysis in areas of highest emission reduction potential is suggested to ensure soil health and climate mitigation balance.

THERAPEUTIC LANDSCAPES AS A PUBLIC HEALTH RESOURCE

***Kitija Graudiņa, Ilze Stokmane**
Latvia University of Life Sciences and Technologies, Latvia

Abstract
Increasing rates of stress-related disorders, mental health challenges, and population ageing have intensified the need to reconsider the role of outdoor environments in supporting public health and well-being. Recent studies combining knowledge from various fields show that everyday contact with nature and thoughtfully designed outdoor spaces can significantly contribute to psychological restoration, stress reduction, and improved quality of life across different age groups. Therapeutic landscapes represent an approach that bridges landscape architecture, environmental psychology, and health-related research, focusing on the interaction between people and their surrounding environments. While this concept has been widely explored within clinical and rehabilitation settings, its potential application as a preventive and supportive element within everyday living environments remains insufficiently systematized. The aim of this paper is to examine the theoretical foundations and key planning principles of therapeutic landscapes, with particular attention to their relevance for mental health support in an ageing society. The study combines a qualitative literature review with a comparative case study analysis of three rehabilitation institutions in Latvia – *Līgatne*, *Tērvete*, and *Vaivari* – evaluating the implementation of therapeutic landscape planning principles in practice. The paper identifies and systematizes core principles of therapeutic landscape design, including sensory engagement, spatial diversity, accessibility, safety, and the role of universal design in creating inclusive environments. The findings highlight the importance of integrating therapeutic landscape principles into contemporary outdoor environment design as a long-term strategy for enhancing public health and mental well-being.
Keywords: therapeutic landscapes, healing environments, mental well-being, landscape architecture, universal design.

Introduction

Modern society faces a range of global challenges that directly affect human health and quality of life. Increasing levels of urbanisation, socio-economic instability, and changes in lifestyle have contributed to the growing prevalence of stress-related illnesses and mental health disorders. Studies indicate that stress is one of the most significant health problems in Europe, affecting a considerable proportion of the population. At the same time, demographic trends point to a rapidly ageing society, which increases the demand for health-promoting living environments and rehabilitation opportunities (Mental health at work, n.d.; Mental health in Latvia, 2022).

In this context, increasing attention is being paid to the quality of the living environment and its impact on human physical and psychological well-being. Landscape architecture and urban planning can serve as important tools for promoting public health, as well-designed outdoor environments can help reduce stress, improve mental well-being, and encourage social interaction (Souter-Brown, 2015).

The theoretical foundations of therapeutic landscape planning principles can be traced to health geography, where Gesler first introduced the concept of therapeutic landscapes in 1992 while investigating why certain environments evoke a sense of healing and contribute to well-being. These environments were defined as therapeutic landscapes – spaces in which the physical and built environment, social conditions, and human perception interact to create an atmosphere conducive to healing (Gesler, 1992).

The concept of therapeutic landscapes is based on the assumption that natural environments and landscape elements can positively influence human psychological and physical conditions. Historically, people have long associated natural environments with healing properties, and in many cultures natural settings have been used for both spiritual and physical restoration (Pouya et al., 2015). Gesler also emphasised that the healing process is not determined by a single element but rather by a combination of environmental components, including physical, social, and symbolic dimensions (Gesler, 1992).

In the literature, several terms are used within the context of therapeutic landscapes, such as healing gardens, therapeutic gardens, sensory gardens, and rehabilitation landscapes. Although these terms are often used interchangeably, they share a common goal—to create environments that support human health, well-being, and recovery processes (Belčáková et al., 2018; Cooper Marcus & Sachs, 2013). Previous studies have largely focused on the use of therapeutic gardens in healthcare institutions such as hospitals, sanatoriums, and rehabilitation centres. However, increasing attention is being given to the potential integration of therapeutic landscape principles into broader living environments, including public outdoor spaces and urban settings (Souter-Brown, 2015).

Considering the growing challenges related to public health, as well as the needs of an ageing population, the integration of therapeutic landscapes into contemporary outdoor planning is becoming increasingly relevant. The aim of this paper is to analyse the theoretical foundations of therapeutic landscapes and to identify key planning principles that contribute to the development of health-supportive outdoor environments.

In addition to the theoretical analysis, the study includes a comparative assessment of three rehabilitation institutions in Latvia – *Līgatne*, *Tērvete*, and *Vaivari*. These case studies were selected because they represent different geographical contexts, rehabilitation environments, and levels of outdoor spatial development, allowing evaluation of therapeutic landscape principles in real-life settings.

Materials and Methods

The study is based on a qualitative analysis of scientific literature aimed at identifying and systematising the planning principles of therapeutic landscapes and their significance in the context of public health. The analysis included scientific articles, monographs, and international studies examining the interaction between natural environments, landscape architecture, and human health. Particular attention was given to research on therapeutic landscapes, healing gardens, and rehabilitation landscapes that analyse the impact of these environmental types on physical and mental health.

During the literature analysis, the main theoretical concepts and approaches characterising therapeutic landscapes across different disciplines were identified, including landscape architecture, environmental psychology, and public health research. Based on the collected information, a conceptual analysis was conducted to identify and systematise the key principles of therapeutic landscape design, including spatial diversity, sensory engagement, safety, accessibility, universal design, and opportunities for social interaction in outdoor environments.

To evaluate how the therapeutic landscape planning principles identified in the literature are implemented in practice, a comparative assessment of three rehabilitation institution territories in Latvia was conducted. The selected case-study sites included the rehabilitation centres Līgatne and *Tērvete*, as well as the National Rehabilitation Centre *Vaivari*.

The selected institutions also differ in terms of accessibility, surrounding natural conditions, spatial organisation, and functional structure, providing a broader understanding of rehabilitation landscape development opportunities in Latvia.

The assessment of the territories focused on spatial structure, accessibility, diversity of outdoor functions and activities, environmental quality, natural elements, and the overall suitability of the outdoor environment for rehabilitation and psychological restoration.

To evaluate the outdoor environments of the selected rehabilitation institutions, developed evaluation matrix of therapeutic landscape planning principles was created based on the theoretical findings identified in the literature analysis. The matrix enabled a structured and comparative assessment of the analysed territories according to key therapeutic landscape criteria (Table 1).

The matrix included several environmental and spatial quality criteria, including spatial diversity, functional zoning, safety and orientation, accessibility and universal design, physical and emotional comfort, availability of activities, and the presence of natural elements within the landscape. Each criterion was evaluated using a qualitative five-point Likert scale, where 1 indicated insufficient integration of therapeutic landscape principles and 5 indicated a high-quality and well-integrated therapeutic environment.

The evaluation matrix was applied to all three rehabilitation institution territories in order to identify strengths, deficiencies, and development opportunities in relation to therapeutic landscape planning principles. This approach allowed the comparison of different rehabilitation environments and provided a practical application of the theoretical principles identified during the literature analysis.

Table 1

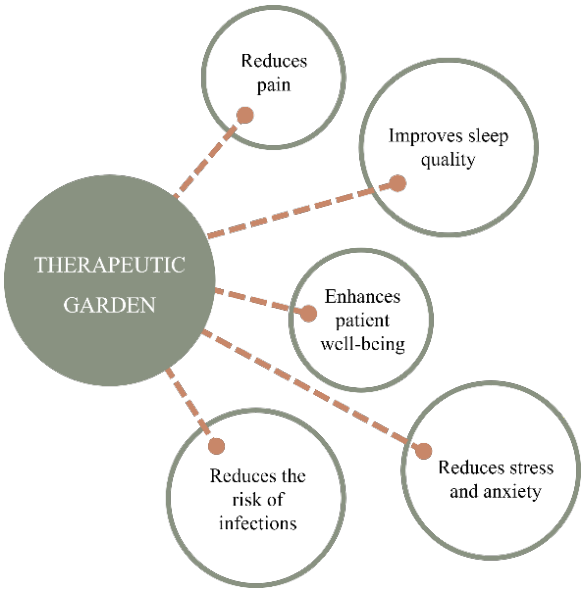
Basic principles of therapeutic landscape planning assessment matrix (authors table, 2023)

Criterion	1	2	3	4	5
Variety of spaces	1-3 different rooms		Up to five different rooms		Eight different rooms
Variety of activities	Uniform activities dominate (e.g. walking areas)		Both active and passive activities. Ability to choose from at least three activities (e.g., walking, some sport, gardening)		A wide range of activities, the ability to operate in any weather and season. There is lighting to use the outdoor area in the dark.
Physical and emotional comfort	Rarely placed benches, resting places are not inviting (physically, emotionally outdated elements). Elements create a reluctance to stay		There are areas that create negative emotions (e.g., outdated, questionable elements), but most of the territory is clean, organized, and pleasant to stay in.		Enough space for recreation, harmony between the architecture and the surrounding environment, it is not heavy. There are no aspects that cause emotional doubts (old, withered trees, overgrown water bodies, untidy environment)
Accessibility	Accessibility of the environment is not ensured, visitors with physical disabilities can only get into the premises with the help of an assistant		Partially accessible. There are rooms that anyone can visit without assistance. Other rooms require the assistance of an assistant.		Everyone, regardless of age, physical and emotional abilities, has the opportunity to access all spaces
Sensory stimulation elements	Uniform materials, greenery, no safe way to touch plants, elements, etc.		There is a variety of vegetation or materials. There are valuable views, but they are not highlighted.		Ample opportunities for sensory stimulation. Variety of materials/textures in both elements and greenery. Emphasizes valuable views, includes water features
Vegetation diversity	No greenery groups have been created, naturally formed vegetation (trees, shrubs) dominates.		Existing vegetation dominates, but separate groups of greenery have been created, which include flowering plants.		Diverse greenery (flowering, of different colors, textures, sizes, foliage). Existing vegetation preserved (large trees, shrubs, ground cover)

Criterion	1	2	3	4	5
Entrance quality	No specific entrance to the territory can be read. The entrance overlaps with the flow of cars.		There are readable entrances. There are several of them - it is difficult to distinguish which is the main entrance, which will lead to the goal		A clearly defined entrance is highlighted, accentuated, inviting.
Safety	No fencing, several aspects that create a feeling of insecurity (e.g. traffic flow)		Partially fenced area. There is no physical fence, but the boundary is formed by other aspects (greenery, forest, etc.)		The territory is completely fenced, there are several components that create psychological and emotional security
Accessibility	There are no memorable elements in the area, on the contrary, negative associations are formed.		Partially recognizable, there are spaces, elements that are associated positively, as well as spaces, elements that create a negative experience		The territory has several elements, zones, views, etc. that create positive emotions, thus remaining in the memory.
Legibility and orientation	Incomprehensible movement spaces make you ask the question - would you dare go there?		Easy-to-read walking routes, but not all trails lead to destinations or building entrances		Fully understandable and readable pedestrian paths, all paths lead to a specific destination or building entrance. No abstract elements

Results and Discussion

The literature analysis on the concept of therapeutic landscapes and related studies allows the identification of several key planning and design principles that contribute to human psychological and physical well-being in outdoor environments. These principles are based on an interdisciplinary approach that integrates research from landscape architecture, environmental psychology, and public health (Belčáková et al., 2018; Souter-Brown, 2015).



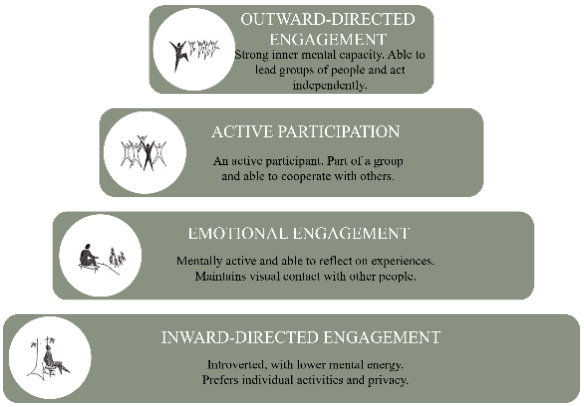
The analysed sources emphasise that therapeutic landscapes are not merely aesthetically designed green areas but carefully planned environments in which natural elements, spatial structure, and user needs interact to create spaces that support psychological restoration, stress reduction, and social well-being (Ulrich, 1999; Cooper Marcus & Sachs, 2013).

Rehabilitation landscapes, which in the context of healthcare institutions' outdoor environments can be viewed through the concept of healing gardens, provide important support in challenging life situations and can complement traditional medical treatment methods. They do not replace medical care or therapeutic procedures but rather function as a supportive mechanism that contributes to faster and higher-quality recovery outcomes (Figure 1). When discussing health, it is essential to consider the interrelationship between physical and psychological factors, which influence one another. Based on this principle, natural environments or environments dominated by natural elements can affect not only physical health but also psychological well-being (Belčáková et al., 2018; Constitution, n.d.).

The results of the study identified several key components that characterise successful therapeutic landscape design. These include spatial diversity and functional zoning, the provision of safety and orientation within the environment, the creation of sensory experiences, accessibility and the integration of universal design principles, as well as the presence of natural elements, particularly water, within the landscape (Pouya et al., 2015; Thaneshwari et al., 2018; Souter-Brown, 2015). The interaction of these principles creates an environment that can support both physical activity and psychological restoration.

Figure 1

Benefits of healing gardens (authors scheme, 2023)

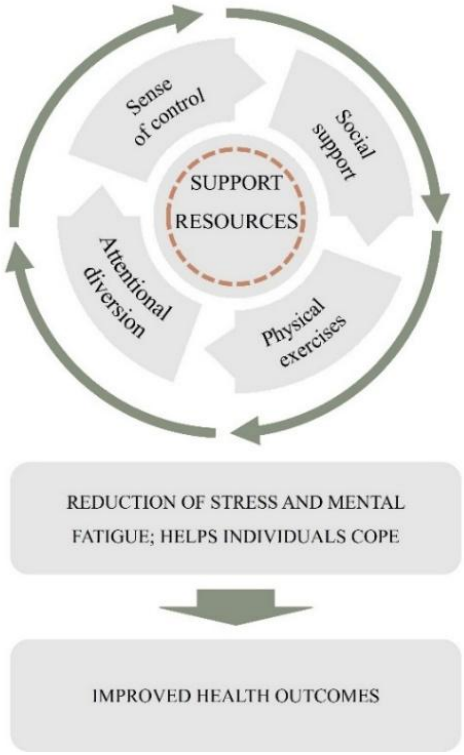


Creating a healing environment requires the combination of two essential aspects: the creation of place and the facilitation of the healing process. Understanding how people perceive their environment and how they respond to it is one of the most important components of therapeutic design. A key aspect involves recognising the relationship between the physical and social environment and human functioning. The pyramid model (Figure 2) illustrates how individuals may have different environmental preferences depending on their mental and physical condition at a given moment (Shahrad, 2012; Stigsdotter & Grahn, 2002).

At the base of the pyramid is inward-directed engagement, where individuals prefer solitude. At this level, mental capacity is relatively low, and activities tend to be private, such as walking or quietly observing

the surroundings. As mental energy increases, individuals may begin to prefer more active engagement with their environment. The second level represents emotional participation, where visual contact with other people becomes important. The next level is active participation, in which individuals seek to be involved in a specific group and engage in shared activities with others, demonstrating a willingness to interact, share experiences, and express creativity. At the top of the pyramid is outward-directed engagement, where individuals possess high mental energy and may take on leadership roles within a group. At this level, people can act independently without requiring external support.

Figure 2
Pyramid of Engagement (authors scheme, 2023, based on Shahrad, 2012)



A therapeutic garden should therefore be able to interact with its users at different levels of engagement. When mental energy is low, individuals may require greater privacy and a less demanding environment. As mental capacity increases, the level of engagement with the environment also increases, enabling more active and socially oriented activities (Ottosson, 2001; Shahrad, 2012).

Considering the impact of stress on human health, it can be argued that gardens within healthcare institutions can improve health outcomes to the extent that they effectively support recovery from stress. The concept of stress provides a foundation for developing scientifically grounded theories of supportive garden design, which conceptualise environmental characteristics and design approaches in relation to their potential impact on health. In this context, the term supportive refers to outdoor environments with environmental features that help patients, visitors, and healthcare staff cope with stress (Ulrich, 1999).

Considering both the impact of stress and the varying levels of human engagement in surrounding activities depending on mental and physical conditions, the surrounding landscape or garden should be able to provide four main supportive resources (Figure 3).

Sense of control – an important factor influencing an individual's ability to cope with stressful events or situations. By helping patients regain a sense of personal control and capability, the recovery process can be accelerated. Visitors to the garden should be aware of its existence, be able to find it easily, and understand how to use the space either actively or passively. Therefore, wayfinding and accessibility are important considerations in garden planning and design (Pouya et al., 2015; Ulrich, 1999).

Figure 3
Support resources provided by the gardens (authors scheme, 2023)

Social support – the garden can serve as an environment that promotes social and emotional support. Group activities, shared physical exercises, horticultural therapy, and informal conversations encourage users to meet others, share experiences, and receive emotional or practical support. Such interactions can help restore self-confidence and support the healing process. Garden design should provide convenient access to different spaces while avoiding layouts that excessively encourage interaction to the extent that it compromises personal privacy (Pouya et al., 2015; Ulrich, 1999).

Physical activity – strengthens both the body and the mind. The garden should motivate individuals to leave indoor environments and encourage them to spend as much time outdoors as possible. It should also provide opportunities to participate in various activities offered within the garden environment (Pouya et al., 2015).

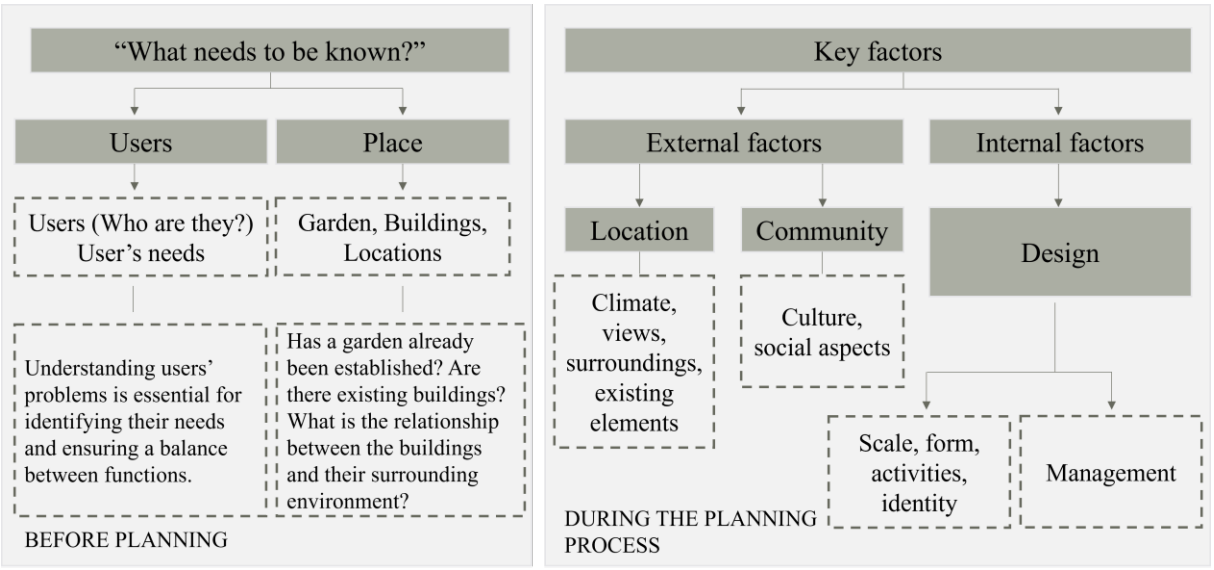
Positive distraction – refers to environmental features that attract visitors' attention and help divert them from negative thoughts or emotions. Such elements can contribute to improved physiological and

psychological responses, including reduced stress levels and improved blood pressure. Examples include water features, flowers, and natural sounds that stimulate sensory engagement (Pouya et al., 2015).

A prerequisite for these previously mentioned stress-reducing resources to be effective is that the garden must create a sense of safety. If the garden design or its location generates a feeling of insecurity or risk, the environment will produce stress and negative experiences rather than promote restoration, and patients may avoid using the garden altogether (Ulrich, 1999).

Based on certain interpretations and viewpoints, any natural garden or park could be considered a healing environment. However, the design of therapeutic gardens is intentionally developed so that their healing and restorative effects can be utilised as effectively and sustainably as possible (Belčáková et al., 2018).

When planning such specialised gardens, it is important to understand the key development processes before initiating the design phase, as well as during the planning process itself (Figure 4). Two main aspects must be considered prior to the planning stage: first, identifying and understanding the potential users of the garden, and second, assessing the physical site where the garden is intended to be developed. Equally important is the recognition of key factors that influence the design during the planning process (Shahrad, 2012).



Understanding user groups and their needs

Before initiating the design process, it is essential to identify the potential user groups. In the planning of therapeutic gardens, primary attention should be given to the people who will use the garden, and this theoretical aspect should serve as a guiding framework for design decisions. To determine the needs of potential users, it is necessary to understand the problems they experience and, accordingly, identify the types of interventions and solutions required.

Depending on the target user groups, a balance should be maintained between opportunities for physical activity and possibilities for passive engagement with the garden environment. Essentially, it is necessary to understand which groups of people will use the garden by addressing questions such as: Who are they? What activities do they engage in? Understanding how individuals perceive their surrounding environment, how they respond to it, what they observe, and how they interpret it is one of the key factors in therapeutic design (Shahrad, 2012; Stigsdotter & Grahn, 2002).

Figure 4

Progress of the rehabilitation landscape planning process (authors scheme, 2023, based on Shahrad, 2012)

At the initial stage, it is also necessary to obtain comprehensive information about the physical location of the garden. All relevant baseline information about the site should be collected. One important aspect of site analysis is accessibility and transportation, ensuring that the area can be conveniently reached not only by private vehicles but also by public transport. It is important to understand where the site is located, what surrounds it, and what specific characteristics define the place. The analysis should identify which site components are valuable and which are less significant. Climatic conditions, prevailing winds, and sun exposure are also important factors. Additionally, it is necessary to determine whether a garden already exists within the site and assess its development potential. Another important consideration is whether there are existing buildings within the territory and how these buildings interact with the surrounding environment (Shahrad, 2012).

During the planning process, two types of key aspects must be considered: external factors and internal factors. External factors mainly originate from the broader social context and the characteristics of the site, while internal factors are directly related to the specific design approach of each individual garden.

A significant portion of design concepts and their

implementation is influenced by external factors. Location is one of the primary aspects of site analysis, as it is shaped by the surrounding environment, climate, and existing landscape elements. There is a substantial difference between a garden located in an urban environment and one situated in a rural area outside the city. Views and the surrounding landscape are important elements that can either enhance or diminish the overall value of the garden. Therefore, perspectives that offer attractive views throughout different seasons should be emphasised, while less appealing views should be visually screened. A therapeutic garden should also provide a variety of activities.

The surrounding environment plays an important role in encouraging visitors to engage in different types of activities, ranging from sitting, resting, and observing the landscape to walking or listening to natural sounds (Shahrad, 2012).

The task of the garden designer is to select the most appropriate locations for different activities to encourage visitors to spend more time outdoors. The surrounding environment should be utilised both physically and visually. Designing gardens within natural settings, incorporating natural sounds and locations outside densely populated areas, helps create a sense of being ʻaway' from everyday routines, which is one of the key qualities sought in healing environments. In this sense, a garden may function as a simple place that contrasts with the complexity of modern society (Shahrad, 2012).

Existing elements within the site are just as important as the surrounding environment. These values may vary considerably—for example, a garden with mature trees and shrubs has a different character compared to an empty plot of land. Integrating existing elements into the emerging design concept is an important aspect of therapeutic garden planning, as it reflects the identity, values, and historical context of the place. The geographical and historical context of a site is particularly important, as it demonstrates how the place has evolved over time and explains why it appears as it does today (Shahrad, 2012; Stigsdotter & Grahn, 2003).

Society, through cultural and social aspects, forms the second component of external factors. It is important to understand the social context in which the garden is being developed and the characteristics of horticultural culture within that society. This includes understanding how well the society recognises the relationship between nature and health, the healing potential of natural environments, and the role of gardening in supporting well-being (Shahrad, 2012).

Internal factors, on the other hand, reflect the specific **design** and development approach of each individual garden. A therapeutic garden should be both functional and aesthetically appealing to attract visitors and effectively respond to users' needs. Maintenance considerations also play an important role in the design process. From a management perspective, factors such as the appropriate size of the garden, the types of vegetation, and the landscape elements to be included should be carefully evaluated (Shahrad, 2012).

To evaluate how the therapeutic landscape planning principles identified in the literature are implemented in practice, three existing rehabilitation facility territories in Latvia were analysed in this study. The assessment of such territories makes it possible not only to evaluate the application of theoretical principles in real environments but also to identify potential challenges and development opportunities in the creation of health-promoting outdoor spaces. Outdoor environments in rehabilitation institutions are particularly important, as they serve as part of the treatment and recovery process, providing patients with opportunities to spend time in natural surroundings, engage in physical activities, and experience psychological restoration.

Within the framework of the study, three rehabilitation facility territories in Latvia were analysed: the rehabilitation centre *Līgatne*, the rehabilitation centre *Tērvete*, and the National Rehabilitation Centre *Vaivari*. The characterisation of these territories is based on an assessment of the existing conditions, with particular attention given to spatial structure, the presence of natural elements, accessibility, and the potential use of outdoor spaces within the rehabilitation process.

To evaluate the outdoor environments of the aforementioned healthcare institutions according to therapeutic landscape planning principles, an evaluation matrix of planning principles was developed. The matrix analysed several key environmental aspects, including spatial structure, functional diversity, sense of safety, physical and emotional comfort, availability of activities, and environmental accessibility. Such an approach enables a systematic comparison of outdoor environments in different rehabilitation institutions and allows the assessment of their compliance with therapeutic landscape planning principles.

The analysis shows that the rehabilitation centres *Līgatne* (Figure 5) and *Tērvete* (Figure 6) are in relatively similar situations, where certain environmental components reveal deficiencies or are insufficiently developed. In the territory of the rehabilitation centre *Līgatne*, the lowest-rated components were physical and emotional comfort, as well as the limited diversity of available activities. In contrast, the outdoor environment of the rehabilitation centre *Tērvete* received the lowest evaluation in terms of spatial diversity and the sense of safety within the territory. In both institutions, a lack of universal design and environmental accessibility was also observed, which may limit the full use of the territory by different user groups.

A different situation can be observed at the National Rehabilitation Centre Vaivari, which is considered one of the most successful examples of rehabilitation landscapes in Latvia. The evaluation of the territory

based on the planning principles matrix showed that many of the analysed components in this territory received the highest scores (Figure 7).

Figure 5
RC Līgatne assessment (authors scheme, 2023)

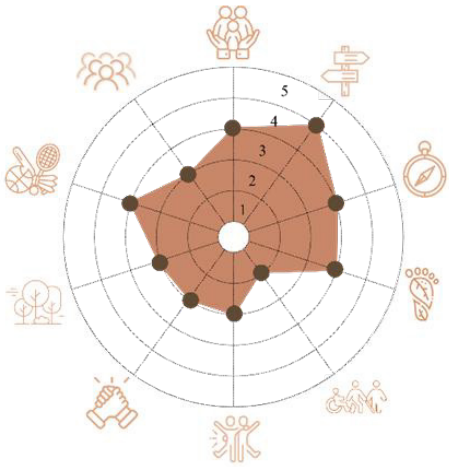


Figure 6
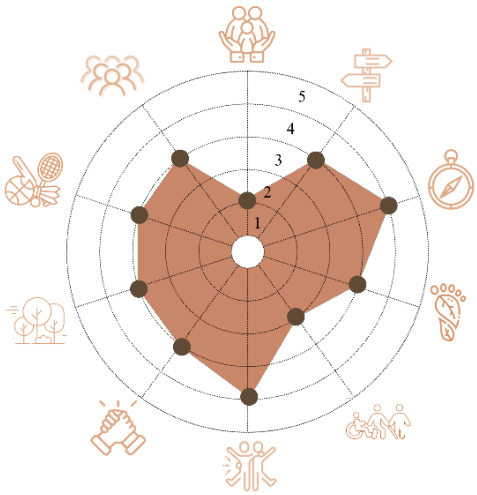
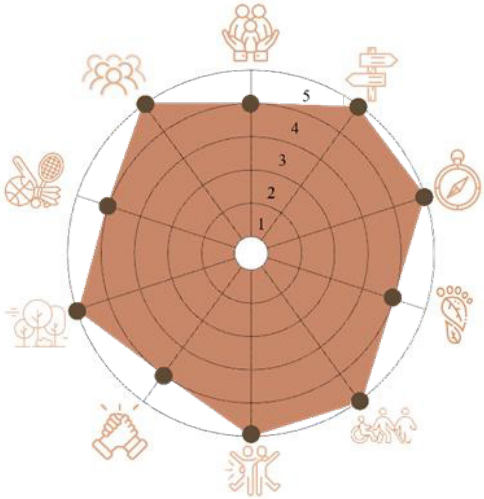
RC Tērvete assessment (authors scheme, 2023)





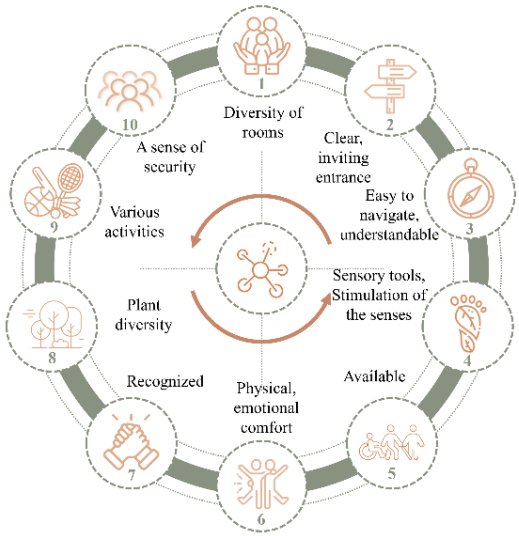


Figure 7
NRC Vaivari assessment (authors scheme, 2023)

An important factor in the development of the centre is its location—it is easily accessible and situated in a resort town, where tourism also contributes significantly to the development and use of the territory. In addition, the high environmental quality of the area is supported by natural factors, particularly the proximity to the sea, which creates favourable conditions for the rehabilitation process. Basic principles of rehabilitation landscape planning their evaluation within the analysed territories are illustrated in Figure 8.

Figure 8
Basic principles of rehabilitation landscape planning (authors scheme, 2023)

The spatial and functional quality of a healing garden is closely related to a complex set of interrelated planning principles (Stokmane & Graudina, 2024) that determine the therapeutic potential of the environment and the psychophysiological responses of its users.

1. Sensory experience and environmental diversity

The quality of a healing environment is significantly determined by its ability to engage all human senses. The diversity of materials and vegetation – various textures, forms, colours, and scents – supports mindfulness practices and fosters a stronger connection with the surrounding environment (Shahrad, 2012). In plant selection, preference should be given to a wide variety of species, including those that create sound in the wind, attract birds and butterflies, and mark seasonal changes, thereby creating a sense of cyclical rhythm and continuity (Pouya et al., 2015). Water elements are particularly valuable: moving water acts as a natural sound buffer and calming visual stimulus, while still water promotes meditation and psychological tranquillity (Pouya et al., 2015).

2. Sense of safety, orientation, and accessibility

A healing environment must ensure both physical and psychological safety for its users. A clear spatial structure – including legible pathways, landmarks, and signage that consistently lead back to building

entrances – reduces the risk of disorientation, which can otherwise trigger anxiety (Pouya et al., 2015). In addition to clear orientation, the environment should evoke familiarity and a sense of security. Recognisable elements, distinctive planting compositions, or water structures can stimulate positive memories and foster a sense of belonging (Erbino et al., 2015; Pouya et al., 2015). The principle of universal design ensures that the garden is accessible to all users regardless of age or physical ability. This includes appropriate pathway widths, suitable surface materials, and seating areas systematically placed approximately every 25 metres (Cooper Marcus & Sachs, 2013; Pouya et al., 2015).

3. Spatial diversity and opportunities for choice

A high-quality healing outdoor environment provides a variety of spaces that correspond to different user needs and emotional states. Secluded and quiet areas for individual rest and reflection, alongside socially active spaces for small or larger groups, provide users with a sense of control over their environment – a factor closely associated with stress reduction (Pouya et al., 2015; Ulrich, 1999). The balance between active and passive zones should be adapted to the specific user group and their capacity and willingness to engage in activities (Shahrad, 2012). Another important aspect is the usability of the garden throughout different seasons and weather conditions. Shelters, semi-enclosed areas near entrances, and appropriate lighting can ensure year-round accessibility (Belčáková et al., 2018; Pouya et al., 2015).

4. Aesthetic quality and positive emotional messaging

The entrance area of a garden forms the first impression and plays a crucial role in shaping the visitor's psychological readiness. It should therefore be representative, welcoming, and evoke a sense of safety (Pouya et al., 2015; Shahrad, 2012). The architecture of buildings, artistic elements, and the overall composition of the garden should create a harmonious and non-oppressive environment, as negative visual associations may intensify feelings of distress among vulnerable users (Shahrad, 2012). Reducing the proportion of hard surfaces and emphasising green vegetation enhances the perceived naturalness of the environment, which – according to the stress recovery theory – is one of the key factors supporting restoration and recovery (Ulrich, 1984).

5. Integration of biophilic design

In contemporary therapeutic landscape planning, increasing importance is placed on the principles of biophilic design, which expand the concept of sensory experience by providing a more systematic framework for strengthening the human–nature relationship. Biophilic design elements – such as natural lighting, natural ventilation, organic materials, and access to green areas – have been associated with reduced stress levels, shorter recovery times, and improved patient engagement (Kellert & Calabrese, 2015). Kellert identified three primary ways in which nature is experienced within built environments: direct contact with natural elements, indirect representations of nature, and spatial relationships that reflect natural forms and structures (Kellert & Calabrese, 2015). Biophilic design has the potential to reduce stress, improve cognitive functioning and creativity, enhance well-being, and accelerate recovery (Browning et al., 2014). Therefore, integrating biophilic design in healing gardens is not merely an aesthetic decision but also a scientifically supported therapeutic strategy.

6. Cultural identity, intergenerational interaction, and community engagement

The effectiveness of healing environments depends not only on their physical and sensory qualities but also on their ability to reflect the social and cultural identity of their users. Successful therapeutic landscapes integrate principles of biophilic design, adaptive resilience, sensory calibration, social granularity, and cultural resonance, offering solutions that promote public health and community resilience. Culturally relevant plantings, design motifs, and spatial arrangements create environments that strengthen a sense of belonging and enrich user interaction with the therapeutic space.

A particularly important aspect is the inclusion of elements that encourage intergenerational interaction. Spaces intentionally designed for contact between different generations not only strengthen social connections but also address the diverse needs of different user groups. Community participation in the design process – through participatory strategies during diagnostic and planning phases – is also a prerequisite for ensuring that healing outdoor environments truly respond to the needs of the specific community and produce long-term therapeutic outcomes (Quiroz Saavedra & Cruz Covarrubias, 2026).

Conclusions

1. The conducted literature analysis confirmed that therapeutic landscapes represent an interdisciplinary approach that combines principles of landscape architecture, environmental psychology, and public health. The analysed studies demonstrated that natural environments can support psychological restoration, reduce stress, and contribute to overall well-being, particularly within healthcare and rehabilitation settings.

2. The study identified several key therapeutic landscape planning principles that are essential for creating health-supportive outdoor environments. The most significant components include spatial diversity, accessibility, safety and orientation, sensory engagement, universal design, and the integration of natural elements such as vegetation and water features. The interaction of these components creates environments that support physical activity, psychological restoration, and social interaction.

3. The comparative assessment of rehabilitation institutions in Latvia revealed considerable differences in the implementation of therapeutic landscape principles. The evaluation matrix demonstrated that

the National Rehabilitation Centre *Vaivari* showed the highest level of integration of therapeutic landscape planning principles, particularly in terms of accessibility, spatial quality, and environmental functionality. In contrast, rehabilitation centres *Līgatne* and *Tērvete* showed deficiencies related to spatial diversity, accessibility, activity opportunities, and emotional comfort, which may limit the therapeutic potential of these outdoor environments.

4. The results of the study indicate that many rehabilitation institutions in Latvia possess high natural landscape potential; however, this potential is not always fully utilised in the development of health-promoting outdoor environments. The findings highlight the importance of integrating therapeutic landscape principles into the planning and redevelopment of rehabilitation territories in order to improve the quality and functionality of outdoor spaces within the rehabilitation process.

5. The developed evaluation matrix proved to be an effective tool for assessing therapeutic landscape quality in rehabilitation environments. The matrix enabled a structured comparison of outdoor spatial characteristics and helped identify both strengths and deficiencies within the analysed territories. The study findings indicate that accessibility, spatial organisation, and diversity of activities are among the most critical factors influencing the usability and restorative potential of rehabilitation landscapes.

6. Considering the increasing prevalence of mental health challenges and the demographic trend of population ageing, the integration of therapeutic landscape principles into healthcare environments, public spaces, and residential areas is becoming increasingly important. Future research could further investigate the application of therapeutic landscape principles within broader urban environments and evaluate their long-term contribution to public health and well-being.

*Corresponding author's email: Eriks.Lingeberzins@turiba.lv

Abstract
Digital solutions and innovative technologies are among key drivers of destination competitiveness, rising awareness, and enhancing attractiveness. This is particularly visible in the meeting and conference industries where place and venue are not sufficient factors any longer to define competitive advantage to attract local and international conference tenders. While sector has been defined as priority export area in Latvia as well application of contemporary digital solutions is among tasks still to be completed to appreciate possible results. Participant delegate cards (badges) are among key features of any business event, conference or meeting, allowing to identify each other and gather valuable attendance statistics. This is also one of areas with high potential to digitalize exiting print-based solutions, though choosing the most appropriate one is an issue with polarized opinions among event organizers, venues and delegates. Digital and reusable conference delegate badge as a competitive advantage has been defined as priority area of development by the conference organizers though service suppliers and in particular smaller event organizers and regional players with lower level of direct involvement in the international business travel may see this as another obstacle to overcome. This article summarizes results of digital badge implementation related research following focus group discussions with industry meeting and event industry representatives and provides in-depth analysis of business environment. Results provide recommendations and a road map to implement what has been defined as 'D-Badge' – an innovative and technologically advanced solution. Research results disclose nuances summarized in scenarios as a framework for further individual actions.
Keywords: digital delegate badges, conference competitiveness.

Introduction

In recent years, conferences and business events have been increasingly influenced by two interrelated developments – the growing emphasis on sustainability and the rapid spread of digital technologies. Conferences are events that generate significant material waste, particularly in the form of single-use participant badges and lanyards, which are often discarded immediately after the event (Mair & Jago, 2010; Getz & Page, 2016). At the same time, conference organisers operate in a highly competitive environment where advantage is achieved through service quality, operational efficiency, and reputational value (Rogers, 2013).

Digital and reusable conference participant badges have been developed as a potential solution addressing both challenges simultaneously. These badges, frequently incorporating QR codes, RFID or NFC technologies, enable the use reusable physical components combined with digital functionalities such as access control, networking, and data collection. While such solutions are increasingly adopted in practice, academic research has largely focused on sustainability, environmental impacts, waste reduction strategies and carbon emissions, while and the importance of digital technologies are analysed separately (Laing & Frost, 2010; Jones et al., 2017), whereas event digitalisation is analysed separately and focuses on visitor experience and smart technologies (Neuhofer et al., 2015). Consequently, the strategic role of digital and reusable badges as a source of competitive advantage remains insufficiently examined.

Recent opinions of the resource-based view emphasise that sustainable competitive advantage depends not only on the value of resources, but on the organisation's ability to effectively embed these resources into organisational processes that support consistent value creation (Barney, 2018; Teece, 2018). Digital and reusable badge systems may contribute to value creation by reducing operational costs, improving data accuracy, and enhancing attendee experience. However, as the technologies are becoming increasingly available, their potential to generate sustained competitive advantage depends on complementary organisational capabilities rather than on the technologies themselves.

From a perspective of sustainability, digital and reusable badge systems are in line with the circular economy principles by extending product lifecycles and reducing material waste (Geissdoerfer et al., 2017). Moreover, sustainability-related practices may contribute to reputational benefits and organisational legitimacy, which are increasingly relevant in attendee decision-making. Nevertheless, the existing literature provides limited empirical evidence on how conference participants perceive such initiatives and whether they are interpreted as meaningful sustainability actions or merely as measures aimed at improving operational efficiency. This is another aspect that highlights the need for further research examining the relationship between digital and reusable badge systems and their competitive advantage.

Conferences and business events face concurrent imperatives to advance sustainability by embracing digitalisation to improve service quality and even brand positioning. Recent reviews show that digital transformation can reinforce sustainability objectives by enhancing operational efficiency, data visibility, and stakeholder engagement, particularly within the service industry (Robertsone & Lapiņa, 2023). In this context, transitioning from single-use and even disposable to reusable, digitally enabled badges

address a salient waste stream while aligning with digitalisation's capability to personalize experiences and streamline interactions (Jiang & Phoong, 2023). More broadly, policy and development analyses emphasize that digital tools can reduce environmental impacts across value chains by improving productivity and resource use, reinforcing the strategic case for integrated digital–sustainability initiatives in events (UNCTAD, 2024).

Digital conference badges employing QR, RFID, or NFC, function as identity, access, and data interfaces enabling expedited check-ins, session-level access control, and contact exchange for networking purposes (Veľas et al., 2024).

While much of the events-related literature treats such tools primarily as experience enhancers, integrated assessments of their sustainability impacts and strategic implications remain limited (Parolin et al., 2024; Chen et al., 2025).

Event competitiveness can be developed across several dimensions − operational efficiency, attendee experience quality and data-driven decision making (Busulwa et al., 2022; Chen et al., 2025). Technology facilitated engagement contributes to these outcomes when coherently embedded across the whole procedure of an event. Recent reviews classify event technologies (including smart, consumer-assistive tools such as digital badges) and link them to enhanced engagement and value creation (Chen et al., 2025). Digital participant badges streamline session-level access control, and enable networking exchanges, thereby reducing friction and elevating perceived service quality (Busulwa et al., 2022). The integration of digital services improves the operational efficiency of conferences by reducing administrative processing time per participant, thereby increasing the ratio of achieved outputs to labor and administrative inputs. This means that, with the same staff capacity, it is possible to serve a substantially larger number of participants, thereby enhancing the operational performance of the conference (Paul et al., 2024; Valášková et al., 2025). Competitive effects depend less on the badge technology per se and more on its integration into organisational routines and complementary assets, consistent with contemporary resource-based theorising that locates advantage in how resources are configured and deployed (Barney et al., 2021). Extending this logic, dynamic capabilities, like sensing, seizing, and reconfiguring, are prerequisites for converting generic digital tools into context specific service innovations and performance gains. The payoff from digital badges scales with CRM integration, personalization rules, data governance, and post-event analytics that enable iterative improvement (Teece, 2007).

Materials and Methods

This study employed a sequential mixed methods design to examine the functional needs and market availability of digital, reusable, and interactive conference participant identification cards. The empirical study was conducted in three consecutive stages. The first stage combined a qualitative focus group interview with a quantitative survey to define the most frequently required functions among industry stakeholders. The second stage comprised a structured desk review and thematic analysis of software platforms and equipment suppliers in accordance with the results obtained in the first stage of the research. Based on the research results from the first and the second stages, a product development scenario matrix was developed in the third stage.

In the first stage, data were collected using a two-step empirical procedure: (a) a focus group interview was conducted to collaboratively identify target use objectives and key functional requirements; (b) a structured survey instrument was subsequently administered to evaluate the perceived importance of the proposed digital participant badges functionalities derived from the qualitative findings of the first stage. In the second stage of the study, a desk-review protocol was implemented to identify and systematically code vendor offerings – both software platforms and hardware solutions, based on information available on websites. Operational definitions were established to differentiate between digital badges, e-badges, virtual badges, and smart badges, with the latter defined as badges incorporating embedded technologies that enable functions such as access control, attendance tracking, networking, and potential payment solutions. In the third stage, building upon the findings obtained in the previous stages, a 2×2 product development scenario matrix was applied. This method enabled the systematic identification and structuring of plausible development scenarios.

In the first stage, the same cohort of industry managers participated in the focus group and structured survey, ensuring population consistency across methods. A total of 32 respondents (92% of the association's membership), representing the sector's leading organisations for which business events organisation is a primary activity, participated in the study. Entities for which business event organisation represent only occasional line of business were purposively excluded from the sample to ensure sectoral relevance and analytical validity. The focus group interview was analysed using thematic analysis, which enabled the identification of the most important themes emerging from the discussion. The relative importance of each identified theme was subsequently examined in the next stage of the study through a structured survey instrument. In the survey phase, only responses from companies with prior experience in the implementation of digital participant badges were included in the analysis. A total of 24 questionnaires were analysed, representing business event, meeting and conference, organizers representing majority of the industry. Descriptive statistics were used to evaluate the perceived importance of eight predefined

functional domains for digital delegate badge implementation. Respondents ranked the domains from 1 (most important) to 8 (least important). Mean ranks and standard deviations were calculated to determine relative priorities. Lower mean ranks indicate higher importance.

During the second stage, a qualitative desk review was conducted to systematically map existing software and hardware solutions to the six use objectives identified in the first stage. Vendor identification was carried out by means of targeted web-based screening of company websites. Thematic analysis was structured through a deductive coding framework derived from the six predefined objectives. For each reviewed vendor, coders recorded the extent to which the six objectives were covered, the enabling technologies employed, the integrations provided, and any differentiating features (e.g., real-time monitoring, alerts for unauthorised access, depth of analytics). Cross-platform comparative matrices facilitated systematic comparison and gap identification, resulting in an aggregated functional landscape of market offerings and highlighting the most comprehensive solution providers. Overall, the software review encompassed 12 platforms, including both Latvian and international providers. Thematic analysis of publicly available website documents was performed to capture the functional scope, enabling technologies, analytical capabilities, and system integrations.

Table 1
Vendor analysis summary

Functionality	Availability	Notes
Registration	Universal	Core feature
Access control	Widely available	Standard implementation
Analytics	Widely available	Varies in depth
Networking	Highly availably	From basic to advanced
Contactless payments	Rarate	Only 1 platform

During the third stage and based on the findings of the desk review, a scenario analysis was conducted to assess the product's commercialisation potential. Scenario development is a strategic analytical tool employed to explore and prepare for multiple plausible futures, particularly under conditions of uncertainty. Scenario planning was selected as an appropriate method given uncertainty about future pathways for a digital, reusable, interactive conference badge. It constructs goal-oriented narratives that explore how objectives, stakeholders, trends, and critical uncertainties may interact.

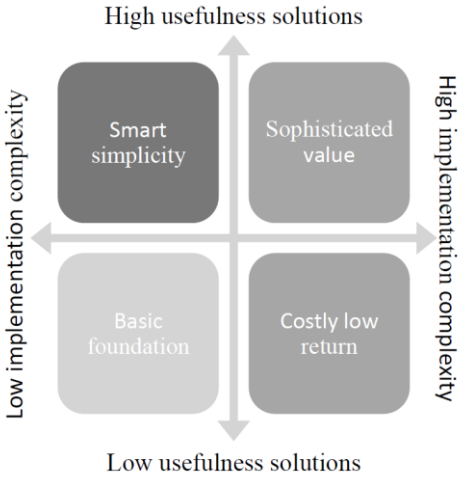
To develop the product development scenarios, a 2×2 scenario matrix was applied, following the methodological guidelines proposed by Rhydderch (2017) and Stucki (2022). In determining the key scenario drivers, the research integrated findings from the stakeholder focus group discussions, product readiness assessment, analysis of available software and hardware solutions, evaluation of technical functionalities, competitive positioning, commercialisation prospects, and risk identification. The synthesis of empirical findings enabled the identification of the principal driving forces contributing to high levels of uncertainty surrounding product implementation, as well as the range of unknown variables potentially influencing its future development trajectory.

Results and Discussion

Based on focus group findings, the identified attributes were consolidated into six overarching functional domains for the proposed digital badge solution. First, digital registration and participant administration encompasses the optimisation of on-site registration procedures, digital badge allocation, participant flow coordination, and badge return monitoring, thereby contributing to operational efficiency and process standardisation. Second, access control and security governance includes role-based and zone-specific access management, controlled entry mechanisms, and security monitoring functionalities, supporting both physical venue management and digital system integrity. Third, networking and structured information exchange refers to functionalities enabling digital contact transfer, scanning-based data acquisition, and facilitated interaction among participants, thus enhancing relational capital formation within business events. Fourth, participant engagement and real-time interaction comprise interactive mechanisms such as live polling, moderated Q&A functionalities, feedback submission, and gamification tools designed to increase active participation and experiential involvement. Fifth, data capture, monitoring, and analytical intelligence incorporates attendance tracking, movement pattern analysis, behavioural data aggregation, and post-event performance analytics, thereby enabling evidence-based decision-making and strategic event optimisation. Sixth, personalisation and experiential enhancement include the provision of customised agendas, tailored informational prompts, and targeted networking suggestions, supporting individualised participant pathways and value co-creation. Beyond these primary objectives, several cross-cutting dimensions were identified as critical implementation contingencies, including sustainability considerations, economic feasibility, technological interoperability with existing platforms, and compliance with ethical and data protection frameworks. Collectively, these findings provide a structured functional taxonomy for evaluating the developmental and commercialisation potential of the 'D-Badge' concept within the business events ecosystem.

The survey's forced-ranking task revealed a clear priority structure: registration acceleration and simplification were the foremost objective (M = 3.79), indicating that operational efficiency and data driven

administrative streamlining dominate organizers' strategic considerations. Overall differentiation across objectives was moderate (mean ranks 3.79–4.71), with access control across event zones receiving the lowest relative priority (mean rank 4.71), suggesting that security related segmentation is secondary in near term implementation planning. Consistent with this pattern, respondents primarily associated digital delegate badges with process optimization and administrative enhancement rather than security centric functions. Variability in evaluations was moderate (SD 1.44–2.96), indicating some heterogeneity in priorities while preserving an overall coherent preference structure within the sample.



Drawing on a review of vendor website documentation for 12 platforms mapped to six use goals derived from stage one, three main results emerged. First, digital registration was universally supported, and most platforms also offered access control and attendance analytics, typically enabled by QR, RFID, or NFC. Second, networking capabilities varied markedly—from basic in-app messaging to algorithmic matchmaking and NFC-based contact exchange—indicating heterogeneous depth across vendors. Third, contactless payments were rare, identified in only one platform, revealing a pronounced capability gap relative to other domains. Integrations (registration systems, CRM, mobile apps, scanners, and published APIs), analytics features, and enabling technologies were systematically extracted from website materials to characterize functional coverage.

Following the results accomplished in first two stages of research, the results of the third stage focus on the assessment of 'D-Badge' implementation scenarios and related factors which determine an overall digital competitiveness of business travel service providers and destinations which have identified business travel as a part of their strategic tourism development plan. Considering the diversity and complexity of the available technological solutions which can enhance participant experience and boost destination competitiveness suggested scenarios are meant to provide a framework for further implementation activities. Furthermore, there has been emphasis to provide insight into applicable development scenarios as a framework for the strategic development of the business segment.

The scenarios developed provide guidelines for destinations focusing on attracting various business events and provide an outline for their regional competitiveness. They are applicable to business related meetings, conferences and events which require delegate registration, attendance monitoring or interaction with the event itself by accessing program, social program, various important information related to the event. The results are targeted at public and private event organisers, venues and regional business travel stakeholders which have identified business travel and its various forms as a strategic development utilizing available infrastructure.

It was concluded that the main criteria to assess the implementation process of 'D-Badge' and to achieve the overall goal of increased destination competitiveness are the functionality aspect (vertical axis) and implementation complexity (horizontal axis). These two forms also main scenario matrix axis, as illustrated in Figure 1. Based on research results for both axis are defined endpoints.

Figure 1
Scenario matrix

The functionality aspect includes usefulness of commercialisation and added value to user. Applying these to an axis on the one end are comprehensive usefulness solutions with high level of such indicators as information personalisation, exchange, real time feedback and on the other end low usefulness solutions with participant identification and simple access to information, primarily using QR codes as the simplest available version.

On the horizontal axis (implementation), stands technological solutions their complexity and related implementation risks. Risks are related to data privacy, required technical equipment and involved supporting staff, while low risks are related to simple integration with minimal technical support compensated by more affordable costs. This axis focuses on resource, knowledge and required organizational tasks to implement digital solutions in business event services. Following identified values and defined axis endpoints, four scenarios were development and named reflecting functionality, added value and implementation risks and complexity as their key values.

Smart simplicity scenario provides high functionality but low implementation complexity. It is scenario where features offer personalized information, networking and it can be useful for medium-sized events with limited IT resources. However, risks are related to integration between other platforms and external NFC providers.

Sophisticated value scenario provides high user value and advanced functionality, but it requires significant resources, hardware and technical support.

Foundation scenario is a low-cost solution which is usually based on QR codes and simple NFC identifications, but they limit functionality and does not provide high level of participant engagement.
Costly low return scenario has high implementation and development costs and provide litter functional value, and it should be avoided whenever possible.

Conclusions

1. A clear assessment of required functionality and technological appropriateness to the aim of digitalization is the key factor in considering making decisions related to enhancement of business event offerings by integrating digital solutions. This is confirmed by the research results where with a median of 3.79 registration simplification has been ranked as the highest priority. The range of available solutions determines the need to focus on the evaluation of required functions.
2. Sustainability and circularity of business event related materials, devices and supportive tools remain a crucial part in overall destination and supplier competitiveness. 'D-Badge' provides an overview of benefits related to the implementation of such reusable tools while decisions of the solution remain case-based and considering the set of aims.
3. NFC, RFID and QR codes remain to be among the most frequently used solutions in event organizations, as explored by the analysis of possible suppliers. The importance of simple and easy to use QR code solutions is decreasing, being replaced by NFC technologies. This is supported by an increased number of mobile solutions used which have entered into everyday life activities.
4. Digitalisation, user-friendly IT solutions, and functionality have emerged as key driving factors of industry competitiveness. Empirical results also show that event organizers primarily associate digitalization with the process of implementing digital badges while security or advanced engagement features have lower level of prioritization. With the spread of easily accessible technologies, this is now applicable also to event organization and related service providers, venues and other stakeholders throughout the public and private sectors. The ability to offer digital solutions determines success in attractive business events such as conferences and meetings which may serve as revenue streams in tourism ecosystems.
5. While in general tourism development remains as a strategic priority for municipalities in Latvia, there are fewer of them which focus not just on leisure travel but also business travel where focus on digitalisation as a tool for strategic competitiveness is important. Among factors influencing regional competitiveness is also the ability to provide contemporary business event delegate solutions. Even the implementation of 'D-Badge' reveals complexity due to a variety of available solutions; the research results illustrate entry level possibilities to start digitalisation of business events also on regional and small-scale levels.

UNEVEN DIFFUSION: THE SECTORAL CONTOURS OF DATA CAPITALISM IN A SMALL OPEN ECONOMY

***Ritvars Metra**
Latvia University of Life Sciences and Technologies, Latvia
*Corresponding author's email: sz19002@lbtu.lv

Abstract
This study investigates the structural penetration of Data Capitalism (DC) within a small open economy, specifically analysing Latvia's 101 most valuable enterprises. Using novel Data-Capitalism Maturity Framework (DCMF), firms are classified into four distinct tiers to determine whether data commodification represents a unified national shift or a phenomenon concentrated in specific sectors. Two hypotheses are tested – first, that the IT & Telecommunications sector exhibits a significantly higher concentration of Primary data capitalists, and second, that data capitalism classification is independent of firm size. Results from non-parametric analyses—specifically Chi-Square, Fisher's Exact, and Cochran-Mantel-Haenszel tests—indicate that the adoption of Data Capitalism (DC) is heavily stratified. Despite comprising only 10.9% of the sample, Primary data capitalists are predominantly located in the IT & Telecommunications sector, which is 35 times more likely to commodify data than other industries. Traditional sectors, such as Manufacturing and trade primarily utilise data for functional efficiency. Additionally, firm size showed no significant association with data maturity tiers, and the IT sector's dominance persisted even after controlling for turnover. The findings conclude that sectoral logic, rather than organisational scale, drives data commodification. Consequently, effective economic policy must be differentiated, prioritising export capabilities for IT firms while enhancing digital integration for traditional sectors.
Keywords: data capitalism, sectoral analysis, firm size.

Introduction

The global economy is undergoing an expansive transition in which the ability to extract, commodify, and exploit data has become a definitive source of competitive advantage (McAfee & Brynjolfsson, 2012; Zuboff, 2022). This shift has given a rise to 'Data Capitalism' (DC). It can be understood as an economic paradigm where data is no longer merely a byproduct of economic activity but a core asset driving value creation (Bolin, 2022). However, this transformation is not a uniform process; its pace and nature are deeply shaped by the unique structural characteristics and technological opportunities of different industrial sectors (Bresnahan et al., 2002). While global technology giants which define the frontier of this new economy are under scrutiny, significantly less is understood about how these dynamics manifest within the diverse industrial contours of small, open economies like Latvia.

Policymakers in regions like Latvia are often tasked to catch up with this new paradigm, yet they lack the granular evidence required to distinguish between sectors that are truly embedded in the data economy and those that are merely undergoing basic digital transformation. Consequently, there is a critical empirical gap in understanding of the actual structural penetration of DC at a sectoral level within a specific national context. It is not quite clear whether the systemic extraction and commodification of data are diffused broadly across the economy or are strictly concentrated within specific industries.

To address this gap, given research empirically assesses the intensity of DC adoption across 101 of Latvia's top enterprises and investigates whether DC represents a unified national shift or it is concentrated in distinct sectoral strongholds.

Furthermore, a critical confounding factor in technology adoption is firm size, as larger firms often possess superior access to capital and talent (Oliveira et al., 2014; Zuboff, 2019). Thus, the research aims to isolate the effect of sector from the effect of size.

With the help of DCMF, the novel framework that categorises firms in four distinct tiers based on their adoption of DC logic, this study is set to determine whether the observed sectoral effects are intrinsic to industry logic or merely artefacts of firms' size. To use turnover as an indicator for firm size is quite a common practice in economic research, used by several scholars previously (e.g. Lestari, 2019; Yasin et al., 2021). To achieve those goals, two specific hypotheses are tested:

H1: The IT & Telecommunications sector exhibits a significantly higher concentration of Primary data capitalists compared to other industrial sectors.

H2: The classification of firms into Data Capitalism tiers is independent of firm size (turnover).

Materials and Methods

The empirical dataset was engineered from the 'TOP 101 of Latvia's Most Valuable Enterprises' list for the year 2024, published by Leading Latvian corporate finance company 'Prudentia' in collaboration with official stock exchange Nasdaq Riga (top101.lv). This list contains a comprehensive cross-section of the 101 economically significant firms operating in Latvia. The sample spans all key economic sectors, such as IT & Telecommunications, Manufacturing & Consumer Trade, Financial Services etc. Financial indicators – including Turnover 2023, EBITDA 2023, and year-over-year Growth – as well as competitive rankings (TOP 2023, TOP 2024), were augmented with the DC tier based on DCMF to provide the quantitative basis for the analysis.

To operationalise the concept of DC, this study employed the DCMF (Mētra, 2026). The framework treats DC not as a binary state but as a continuum

where Primary DC (tier 3) are on the one side and Non-DC (tier 0) on the other with two additional tiers – Secondary DC (tier 2) and Tertiary DC (Tier 1) in the middle.

DCMF assesses firms across four weighted dimensions derived from value creation mechanisms: (1) Data Extraction (20%) – assesses whether data extraction is a core operational activity and a deliberate resource accumulation strategy; (2) Data Commodification (20%) – examines if extracted data is treated as a commodity, through direct monetisation or significant product enhancement; (3) Data Exploitation (30%) – evaluates the use of advanced analytics or AI to exploit data patterns for competitive advantage; and (4) Data Centrality (30%) – determines the extent to which the firm's business model is dependent on data-driven insights for survival.

The classification process involved a mixed-methods approach integrating qualitative analysis with a 'Human-in-the-Loop' (HITL) – AI-assisted methodology. HITL is a procedure in which a person is actively involved in the operation, monitoring or decision-making of an automated system (Stryker, 2025). It is already used in scientific research. For example by Al-Turki et al. regarding RASE tagging in building compliance (Al-Turki et al., 2024) or Umakanth regarding validating GenAI outputs in clinical settings (Umakanth, 2025).

First, the author conducted a systematic review of public documents—corporate websites, annual reports (2021–2023), and press releases for each firm. To ensure reliability and mitigate bias, the classification was validated using two advanced LLMs: Google's Gemini 2.5 Pro and OpenAI's ChatGPT-O3. This validation leveraged the AI's ability to process large text volumes to identify potential anomalies or bias in the human researcher's assessment. In cases of discrepancy, a reconciliation process involving a re-examination of the evidence was triggered. The final classification decision in all cases rested with the human researcher, ensuring that AI remains only as a tool for calibration rather than autonomous decision-maker.

The iteration of DCMF logic proceeded in two blocks. First categorization was performed on random sample data by author and two recruited master level students. First, the author manually analysed the selected companies. For each firm, 'intelligence folders' with annual reports and relevant public documents were created. Subsequently, two independent master-level students were contracted to analyse the same sample using the DCMF (v1.0) protocol. To ensure consistency in the assessment process, the students were given access to 'intelligence folders' together with specific instructions on how to evaluate the firms and calculate the maturity score. Then the same sample data was coded with both LLMs. Both models were provided with the same collated public data and a standardised prompt to perform an independent classification.

The first iteration revealed that earlier version of DCMF overvalued the direct sale of data, underestimating 'walled garden' models where data is exploited internally. Consequently, the final weights prioritise internal transformation and strategic centrality over simple commodification (DCMF v2.0). Each dimension was scored on a four-point ordinal scale (0 = Minimal/None to 3 = Advanced/Extensive), based on verifiable, publicly available information. The scoring protocol is conservative, assigning zero in the absence of clear evidence. The composite DCMF Index Score was calculated as follows:

$$\text{DCMF_Index_Raw} = (Score_{Extraction} \times 0.20) + (Score_{Commodification} \times 0.20) + (Score_{Exploitation} \times 0.30) + (Score_{Centrality} \times 0.30) \quad (1)$$

Firms were then categorised into one of four mutually exclusive tiers based on a sequential logic:

- Tier 0 (Non-Data Capitalist): Data Extraction score is 0 (Gatekeeper Rule).
- Tier 3 (Primary Data Capitalist): (Score ≥ 2 in both Extraction and Commodification) OR (Score = 3 in both Extraction and Exploitation).
- Tier 2 (Secondary Data Capitalist): Remaining entities with DCMF Score ≥ 51.
- Tier 1 (Tertiary Data Capitalist): Remaining entities with DCMF Score ≤ 50.

Integrating the computational efficiency of AI with the critical oversight of a human-in-the-loop framework maximises analytical throughput whilst safeguarding against algorithmic bias and ensuring the contextual validity of the final classifications.

Because of the observed right-skew in financial data, the small sample sizes within certain DC_Tiers, and several missing data points, non-parametric statistical procedures were used. All analyses were performed using the Python programming language (version 3.13.0), with the pandas (1.5.3), numpy (1.24.0), scipy (1.14.1), and matplotlib (3.6.3) libraries.

To control the family-wise error rate across multiple comparisons, the Holm–Bonferroni method was systematically applied. To test H1 (Sectoral Concentration), the sectoral composition of the IT & Telecommunications sector was contrasted against all other industries using a Pearson's χ^2 test on a 4×2 contingency table (Tiers by Sector Group). Effect size was measured using Cramér's V. To identify specific drivers, per-tier contrasts were evaluated using Fisher's exact tests on 2×2 tables, reporting odds ratios (OR) with 95% confidence intervals. To test H2 (Role of Firm Size), independence between DC_Tier and firm size was evaluated using a Pearson's χ^2 test of independence on size quartiles. Given the non-parametric nature of the financial data, a Kruskal-Wallis H-test was also employed to compare raw turnover distributions across the tiers. To ensure that the observed sectoral effects in H1 were not

confounded by firm size, a Cochran–Mantel–Haenszel (CMH) test was conducted. This test pooled the association between IT sector membership and Primary status across the four size strata, yielding a common odds ratio that reflects the relationship independent of firm scale.

These robust statistical methods ensure a reliable foundation for interpreting the complex relationships between data capitalism maturity, industry sector, and firm size.

Results and Discussion

The empirical analysis of Latvia's 101 most valuable enterprises reveals a corporate landscape where data capitalism is not a pervasive, uniform wave, but a stratified phenomenon shaped decisively by sectoral logic. The classification of firms into the DC Tiers using the DCMF yielded a distribution where 'Primary' data capitalists remain a distinct minority, accounting for 10.9% (11 firms) of the sample. However, the economic landscape is not merely binary. The largest segment consists of 'Tertiary' firms (47.5%, n=48). Thus, for almost half of the top enterprises, data remains a supportive resource or functional input rather than a core asset. A significant portion of the sample sits in the intermediate 'Secondary' tier (22.8%, n=23). 'Non-Data Capitalists' comprise the smallest group (18.8%, n=19).

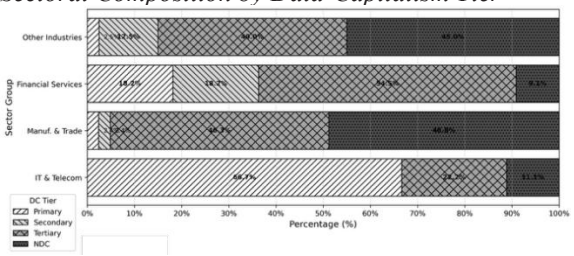
Sectorally, the sample is dominated by Manufacturing & Trade, which represents 45.5% of the firms (46 companies). Next by size is Other Services (20.8%), then Financial Services (10.9%), and IT & Telecommunications (8.9%). Financial profiles across DC tiers reveal a non-linear relationship between size and data strategy. Highest median turnover is found in the Secondary tier (€200.2M). Primary data capitalists (Tier 3) exhibit a robust median turnover of €163.7M. This turnover is substantially higher than €76.4M shown for Non-Data Capitalist tier. Thus, the transition to higher data maturity tiers is generally associated with increased revenue scale.

The first assumption of this research was that the IT and Telecommunications sector would exhibit a significantly higher share of Primary data capitalists than other industries (H1). The analysis provides overwhelming support for this proposition. A 4×2 contingency analysis comparing the tier distribution of the IT & Telecommunications sector against all other industries revealed a statistically significant and strong association ($\chi^2(3) = 32.84$, p <.001, Cramér's V = 0.570). This effect size is substantial, suggesting that sector is a dominant predictor of a firm's data strategy. In contrast to the Financial Services sector ($\chi^2(3) = 5.81$, $p = .121$) or the Manufacturing & Consumer Trade sector ($\chi^2(3) = 8.20$, $p = .042$), which exhibited either no distinction or only modest deviations from the general economic profile, the IT sector stands apart as a distinct 'data-native' ecosystem.

The intensity of this concentration is best illustrated through the odds ratios derived from Fisher's exact tests (Table 1). When isolating the 'Primary' tier, IT & Telecommunications firms are vastly overrepresented.

Table 1

Statistical Association of Sectors with Data Capitalism Tiers



Sector	Focal Tier	Odds Ratio (OR)	95% CI [Low, High]	Fisher's Exact *p* (adj.)
IT & Telecom	**Primary**	**34.80**	**[5.51, 245.05]**	**< .001***
	Tertiary	0.12	[0.01, 0.96]	1.000
Manuf. & Trade	Primary	0.14	[0.02, 1.17]	.182
	Tertiary	1.30	[0.58, 2.89]	.546
Finance	Primary	2.28	[0.42, 12.41]	.596
	Tertiary	1.72	[0.49, 6.05]	.521

Note: *p*-values are Holm–Bonferroni adjusted to control for family-wise error within sectors. Significant results at $\alpha = 0.05$ are bolded.

The analysis yielded an Odds Ratio (OR) of approximately 34.80 (95% CI [5.51, 245.05]; Holm-adjusted p <.001). In practical terms, this indicates that a firm operating in the IT & Telecom sector is nearly 35 times more likely to be a Primary data capitalist than a firm selected at random from the rest of the Latvian economy. Conversely, the sector is numerically underrepresented in the Tertiary tier (OR ≈ 0.12). This finding is reinforcing the binary nature of this divide. It seems that in Latvia IT firms are those that primarily commodify data, whereas firms in other sectors utilise data merely as a functional input. This structural divergence is further illustrated in Figure 1, which details the sectoral composition by tier.

Figure 1

Sectoral Composition by Data-Capitalism Tier

Source: Author's design.

As visualized in Figure 1, the firms in IT & Telecom sector sits dominantly in Primary DC tier (indicated by the darkest shade). They account nearly two-thirds of Primary tier composition (6 out of 9). In sharp contrast, the Manufacturing & Consumer Trade sector is heavyly concentrated in the Tertiary and Non-Data Capitalist tiers (lighter shades).

The visual representation confirms the skew. Figure 1 show that IT sector has internalized data as a core commodity. The traditional sectors remain largely in the value-utilization stages of the data capitalism spectrum.

This finding aligns with the analysis in Andreoni and Roberts, who document pronounced sectoral divergences in digital intensity under platform capitalism, with IT and telecommunications sectors exhibiting high levels of data commodification and digital-native ecosystems, while traditional manufacturing remains largely confined to functional or lower-intensity digital utilization in latecomer economies (Andreoni & Roberts, 2022). In the IT and Telecommunications sector, the core product – whether software code, internet connectivity, or a digital platform—is intrinsically data-based. The marginal cost of duplicating this data for new value streams is near zero, and the infrastructure for data extraction is often pre-integrated into the service delivery mechanism (Parker et al., 2017). For these firms, 'Primary' data capitalism is not a radical pivot; it is a natural result of their existing capabilities.

A critical question in the analysis of technology adoption is whether observed patterns are driven by strategic orientation or simply by resource availability. It is well-established that large firms often have greater access to the financial and human capital required for advanced analytics (Oliveira et al., 2014). Therefore, one might argue that the concentration of Primary data capitalism in the IT sector is merely an artefact of firm size – perhaps the IT firms in the sample are simply larger and thus more capable of investing in data monetisation.

The second assumption of this research was that the classification of firms into Data Capitalism tiers is independent of firm size (H2). For firm size turnover was used as a proxy.

A Pearson Chi-Square test of independence between firm size quartiles and DC tiers yielded a non-significant result ($\chi^2(9) = 16.68$, $p = 0.054$). Similarly, a Kruskal-Wallis H-test comparing the raw turnover distributions across the four tiers failed to reach the threshold of statistical significance ($H = 7.70$, $p = 0.053$. These results indicate that turnover (firm size) is not a deterministic driver of DC maturity.

Looking at the median turnover in each tier further proves that the trend isn't a straight line. While Non-Data Capitalists (Tier 0) exhibited the lowest median turnover (€76.4M), the highest median turnover was actually observed in the Secondary tier (Tier 2) at €200.2M, rather than in the Primary tier (Tier 3), which reported a median of €163.7M. Such distribution indicates that achieving 'Primary' status is not merely a function of economic scale. Many large firms in the sample remain in the Secondary or Tertiary tiers, using data as a support function rather than commodifying it.

To validate H1, determining whether the clustering of Primary data capitalists in the IT sector was an artifact of firm size a Cochran-Mantel-Haenszel (CMH) test was employed. The test assessed the association between sector (IT vs. Other) and Primary status while stratifying firms by size quartiles. The results confirmed that the IT-Primary link is robust and independent of scale. The common odds ratio for being a Primary data capitalist in the IT sector, adjusted for firm size, was 32.56 ($p < .001$). This implies that even when comparing firms of similar size, an IT & Telecommunications firm is nearly 33 times more likely to be a Primary data capitalist than a firm from any other sector. Consequently, sectoral identity, rather than firm size, is the decisive factor in predicting a firm's position at the apex of the data capitalism hierarchy.

This result is of significant theoretical importance. It indicates that when we compare an IT firm and a non-IT firm of the same size, the IT firm is roughly 33 times more likely to adopt a Primary data capitalist model. This confirms that the driver of data capitalism is sectoral logic, not organisational scale. A small IT software provider is structurally more predisposed to monetise data than a massive retail chain or a large manufacturing plant. The retailer may use data to optimise inventory (Tertiary), but the software provider sells the very logic of optimisation (Primary).

The findings of this study offer a corrective to the generalised narratives of the 'Data Economy'. The transition towards data capitalism is often portrayed as a universal imperative—a ladder that all firms must climb to survive (Massa & Tucci, 2013). The empirical results, however, suggest that the ladder exists primarily for specific sectors. The stark concentration of Primary data capitalism in the IT & Telecommunications sector validates the existence of a 'digital native' advantage. These firms possess what Teece describes as dynamic capabilities that are fundamentally aligned with the data economy (Teece, 2018). They do not need to undergo the painful 'digital transformation' that traditional industries face because their assets were digital from birth; their transition to DC is an evolution of their core competency. Conversely, the absence of a statistically distinct profile for the Financial Services sector is a noteworthy 'non-finding'. Despite being an information-intensive industry (Chen et al., 2012), Latvian financial firms do not statistically differ from the general industry baseline in their adoption of Primary data capitalism. This may reflect the 'FinTech paradox': whilst the sector processes immense amounts of data, regulatory constraints (Colangelo, 2024) and legacy infrastructure in established banks often limit their ability to commodify that data directly. They remain high-intensity users (Tertiary) rather than sellers. The lack of a size effect (H2) challenges the Resource-

Based View (RBV) in the context of data strategy (Barney, 1991). Traditional RBV suggests that resources (size, budget) dictate capabilities. However, in the data economy, structural assets (the nature of the product) appear to matter more than financial assets. A small platform company can generate data network effects that a multi-billion-euro manufacturer cannot replicate, simply because the manufacturer's product is rivalrous and physical.

From a theoretical standpoint, these findings support a nuanced view of value creation in the digital age. It is crucial to distinguish between Data-Supported Value Creation (Tertiary), which is applicable across all sectors and involves efficiency and optimisation, and Data-Driven Value Capture (Primary/Secondary), which entails the direct monetisation of data assets. Existing literature frequently conflates these concepts, leading to inflated expectations regarding the transformative potential for traditional industries. The findings suggest that for the Manufacturing and Trade sectors, the 'Tertiary' model does not represent a failure to reach the apex tier, but rather constitutes the appropriate strategic fit for their industrial reality (Kowalkowski et al., 2015). Ultimately, recognising this sectoral dichotomy redefines the trajectory of the digital economy, suggesting that the path to value creation is not a universal ascent towards data commodification, but a strategic alignment with a firm's inherent industrial logic.

DC is neither good nor bad. It is an emerging economic paradigm and must be treated as such. If the national economy can prosper from utilising data as a 'new oil', the government and society might consider it. After all, it is not as if we are sitting on a vast pool of resources, as other nations do. Therefore, from a policy perspective, the implications are distinct. A 'one-size-fits-all' national data strategy is ill-advised; policies designed to foster data driven business models must be differentiated.

For the IT & Telecom sector, policy should prioritise scaling and export: assisting these Primary data capitalists in navigating cross-border data regulations and accessing global markets, given that their product (data or code) possesses global liquidity. Conversely, for the Manufacturing and Trade sectors, the focus should be on adoption and integration: providing incentives for sensor integration, digital twins, and analytics training to maximise efficiency as Tertiary users. Expecting a timber manufacturer to pivot to a data seller model is strategically misaligned; supporting them in utilising data to reduce waste is, however, economically vital.

The independence of data capitalism from firm size suggests that policymakers must not overlook SMEs. Given that smaller IT firms demonstrate a high propensity for Primary tier DC, innovation grants should be accessible to these players, who are often more agile in identifying niche data monetisation opportunities than larger incumbents constrained by legacy models.

Conclusions

1. The empirical analysis of Latvia's 101 most valuable enterprises reveals that Data Capitalism is not a uniform, economy-wide phenomenon, but a highly stratified landscape characterised by distinct sectoral clusters. While nearly half of the sample operates as Tertiary data capitalists, utilising data primarily for operational efficiency, Primary data capitalists remain a distinct minority.
2. The study provides strong support for the hypothesis that sectoral logic is the primary determinant of data capitalism maturity. The IT & Telecommunications sector exhibits a statistically overwhelming concentration of Primary data capitalists; firms in this sector are approximately 35 times more likely to be Primary data capitalists than firms in any other industry.
3. Firm size, measured by turnover, was found to be statistically independent of data capitalism tier. Neither the largest firms nor the smallest are statistically predisposed to achieve Primary status, and the strong association between the IT sector and Primary data capitalism persists even after controlling for firm size.
4. The findings suggest that the structural nature of a firm's core product (whether it is digital or physical) is a more significant driver of data commodification than financial resources or firms' size. Consequently, large traditional firms do not automatically possess superior data strategies compared to smaller technology-focused firms.
5. These results suggest that a 'one-size-fits-all' national data strategy is ill-advised. Policy interventions should be differentiated to support the specific needs of each sector: assisting IT firms with scaling and export capabilities to leverage their global products, whilst supporting Manufacturing and Financial sectors with digital integration tools to maximise efficiency as data users.

Limitations

While these findings offer a robust snapshot of the Latvian economy, they must be interpreted within the constraints of the methodology. The reliance on publicly available data, such as annual reports and websites, means the study captures only publicly disclosed strategic intent. It is possible that some firms, particularly within the competitive financial services sector, employ 'stealth' data monetisation strategies that remain undisclosed to avoid regulatory scrutiny or competitor imitation. Furthermore, as a cross-sectional study of the top 101 firms, this research captures the economic landscape at a single point in time (2023–2024). It does not capture the velocity of change.

Author's note on related work

An extended version of this research is published in scientific peer reviewed journal 'Economics Bulletin' (Mētra, 2026). The present paper should therefore be read as a conference-version contribution from the same research programme. The 'Economics Bulletin' article provides the extended journal treatment of the

sectoral concentration of Data Capitalism in Latvia, including broader hypothesis development and additional performance and mobility tests. The present conference paper retains a narrower focus on the implications of sectoral concentration and firm-size independence for differentiated economic-policy interpretation.

IOT-BASED AUTONOMOUS MONITORING SYSTEM FOR REAL-TIME WASP DETECTION AT BEEHIVE ENTRANCES

***Kirishanth Manivannan, Aleksejs Zacepins**
Latvia University of Life Sciences and Technologies, Latvia
*Corresponding author's email: manikiri001@gmail.com

Abstract
Beekeeping is an established component of agriculture, contributing to both economic output and crop production via pollination services. However, it is increasingly challenged by climate variability, predators, diseases and other stressors. Among these, this study focuses on bee colony protection against predators such as wasps, which can cause substantial colony losses if attacks go undetected. This study develops an IoT-integrated, autonomous three-stage solution intended to detect wasp presence at the beehive entrance and support timely protection. In Stage 1, the Fast Background Subtraction with Adaptive Block Learning (FBS-ABL) model detects motion in downscaled frames extracted from hive-entrance video and produces cropped candidate region. Which will then be processed using a lightweight classifier, MobileOne in stage 2 to label each crop as bee, wasp and background. In this stage, a temporal decision rule then evaluates a short window of consecutive frames and issues an alert that Stage 3 only when multiple wasp occurrences are observed across the window. Finaly in stage 3, YOLO-World v2 performs full-frame detection to localize and confirm wasp presence within the selected window. The beekeeper is alerted only when the Stage 2 indication is corroborated by Stage 3 across multiple frames. This design reduces frequent, expensive calls to the detector and supports low-cost deployment with minimal computational resources, such as a NVIDIA Jetson Nano 4GB, a camera module, a 10 W power supply, and network access. The implemented pipeline achieves near real-time performance at approximately 15 FPS, providing an affordable and reliable near real time warning system against wasp threats at beehive.
Keywords: wasp threat, precision beekeeping, bee colonies, bee hives, autonomous surveillance.

Introduction

Beekeeping has long been practiced in Latvia, as in many other parts of the world, for both food production and medicinal purposes. In 2023, Latvia exported honey worth 1.65 million euros, exceeding the 0.95 million euros spent on imports, reflecting a positive trade balance (Ministry of Agriculture of the Republic of Latvia, 2024). Despite this, the sector demonstrated signs of decline between 2023 and 2024. During this period, honey production fell by 5.4%, the average market price decreased by 3.7%, and the number of bee colonies declined by 2.1% (Central Statistical Bureau of Latvia, 2025). Several factors may explain this downward trend. In 2024, an unusually warm spring caused flowers to bloom earlier and wither more quickly, reducing the period available for nectar collection (Latvian Public Media, 2024). In June, high heat forced bees to spend more energy gathering water to cool their hives, leaving them less time for foraging activity (Zemgale Regional Television, 2024). In addition, although the European Union is the 2nd largest honey producer, it satisfies only about 63% of its internal demand, creating pressure from lower-priced imports (European Commission, 2024). Since honey imported from major external suppliers was sold at a much lower unit value than Latvian honey, this likely intensified market competition and contributed to the decline in Latvia's honey price in 2024 (National Statistical System of Latvia, n.d.). While these external factors are difficult to control, improving internal practices with low-cost solutions could strengthen the resilience and long-term sustainability of the industry. As a member of the European Union, Latvia benefits from access to a large market and already meets quality standards comparing to the external exporters. Moreover, beekeeping plays an essential ecological role, as honeybees are responsible for approximately four-fifths of insect-driven pollination in Latvia, making the sector indispensable to both agriculture and ecosystem stability (Ministry of Agriculture of the Republic of Latvia, 2024).

According to Perichon et al. (2024), the threats affecting beekeeping across European Union countries can be classified into eight categories, one of which is predators, including wasps. This problem has also been observed in Latvia. In 2024, Jelgava Technology Secondary School reported that its bee colonies were frequently exposed to wasp attacks. When such threats are not detected in time, they can have severe effects on colony health and negatively influence honey production. These cases highlight the need for timely predator monitoring. Precision beekeeping offers a practical approach for such early threat detection. Moreover, precision beekeeping has already been introduced in Latvia, which makes further development and application more feasible (Zacepins et al., 2021).

At present, several studies have proposed solutions to address this specific threat, but each has certain limitations. MOG2+CNN and BeePIV were developed mainly for bee counting and estimation of flying direction rather than threat detection, and their performance is affected by shadows and strong dependence on parameter tuning (Kulyukin et al., 2021; Kulyukin & Mukherjee, 2019). This reduces their suitability for real-time threat detection inside hives on low-cost edge devices. DY-RetinaNet was introduced specifically for threat detection; however, it was not designed for low-resource environments, and the study did not provide enough detail to fully assess its computational requirements (Hu et al., 2022). The multimodal system is suitable for edge deployment, but it depends on a specific infrared depth camera and relies heavily on wasp flight paths for

detection (Nasir et al., 2023). While this may be effective for the current task, it limits the adaptability of the system for future extensions. In comparison, image-based features are generally more reliable and more likely to generalize new threats, leaving room for further improvement. The Mask R-CNN with Kalman filtering approach was intended mainly for detecting and tracking individual bees rather than identifying threats, making it computationally expensive and less appropriate for low-cost wasp detection (Kongsilp et al., 2024). YOLO-based approaches have also been used to detect multiple object classes, including wasps (Vdoviak et al., 2025). However, the recommended deployment of hardware, Jetson AGX Orin 64GB, is relatively expensive, which reduces the practicality of this approach for affordable and large-scale deployment.

By analyzing the existing beehive monitoring solutions, it can be observed that motion-based foreground–background separation and object classification or detection are the most commonly used components. However, not all approaches depend on motion-based separation, whereas object classification or detection are used more consistently across the studies. The review of these solutions also shows an extensive use of deep learning models. Although these methods have improved detection performance, they have also increased model complexity, which reduces their suitability for low-cost edge deployment. This is an important consideration for the present research where it aims to provide an affordable solution for autonomous real time detection of wasp threats at the beehive entrance. Another noticeable pattern can be seen in the earlier solutions, such as MOG2 + CNN and BeePIV, which were mainly used for bee counting and traffic direction analysis. These approaches show a link between simpler classifiers, foreground–background separation, and cost-effective deployment. By first separating the foreground from the background, the classifier only needs to process a smaller region of the image, which is sufficient because bees and wasps occupy only a limited part of the frame. Accordingly, this approach could be integrated to develop a viable solution for wasp detection that supports low-cost implementation by reducing computational demand. The proposed solution is therefore divided into three main stages:

1. Use Motion-based object detection techniques to select regions that represent movement between frames extracted from the live video.
2. With a low-cost classifier, search for any appearance of wasp.
3. Use detector on selected frames to localize the threat instead of using such expensive tasks on all frames.

Materials and Methods

a) Stage 1

Following the development of basic architecture, the aim of the first stage is to extract motion regions from consecutive frames in order to identify moving objects at the hive entrance, such as bees and wasps. For this purpose, three categories of methods are considered: traditional background subtraction, optical flow for motion cues, and learned foreground segmentation. To determine the most stable option for the proposed system, one state-of-the-art method from each category is analyzed in Table 1.

Table 1
Analysis of foreground background extraction methods for stage 1

Category	Method	Key Metric	Dataset used	Inference speed	Device	Deep Learning
Traditional background subtraction	FBS-ABL (Montero et al., 2021)	F1 0.6585	Cdnet-2014	277 FPS	I7 3.3 GHz, 16GB RAM	No
				21 FPS	ARM Cortex A9 2-core, 1GB RAM	
Optical flow for motion cues	FastFlowNet (Kong et al., 2021)	EPE 2.08	MPI Sintel clean test set	5.7 FPS	NVIDIA Jetson TX2	CNN
				90 FPS	NVIDIA 1080Ti	
Learned foreground segmentation	Fast BSUV-Net 2.0 (Tezcan et al., 2021)	F1 0.80	Cdnet-2014	29 FPS	NVIDIA Tesla P100 GPU	CNN

Among the evaluated methods, Fast BSUV-Net 2.0 demonstrates higher performance than FBS-ABL when comparing the F1 score. However, this improvement comes with significantly higher computational requirements. Fast BSUV-Net 2.0 achieves an inference speed of around 29 FPS but requires more powerful hardware to operate efficiently. In contrast, FBS-ABL achieves approximately 277 FPS on standard desktop hardware and about 21 FPS on an edge device, making it more suitable for resource-constrained environments. This difference results from the approaches used by the models. Fast BSUV-Net 2.0 belongs to the category of learned foreground segmentation methods, which rely on deep learning architectures to predict foreground masks from video frames. These models generally provide stronger robustness to illumination changes and background dynamics but require greater computational resources and the performance might change based on the training data. On the other hand,

FBS-ABL follows a traditional background subtraction approach, which models a static model and identifies pixels that differ from this model as foreground. While such methods may achieve lower accuracy, sensitive towards changes in environment compared with deep learning approaches, they are significantly more efficient in terms of computational cost and do not depend on the training dataset. Since the objective of this stage is to extract foreground regions while maintaining low computational demand for edge deployment, FBS-ABL represents the most suitable choice. Another method we considered, FastFlowNet, does not report an F1 score, making a direct comparison difficult. Nevertheless, because it is also based on deep learning, it requires higher computational resources similar to Fast BSUV-Net 2.0. For this reason, FBS-ABL is selected as the final method for this stage of the proposed solution.

After selecting FBS-ABL for Stage 1, the method is adapted to better match the requirements of motion extraction at the beehive entrance. Several modifications are introduced to improve its suitability for detecting small moving objects such as bees and wasps. First, the block size is reduced from 16 to 8 to increase sensitivity to small-object motion. Second, instead of linking the background update interval to the frame rate, a fixed update interval is used to provide more stable control over throughput and background adaptation. Third, the smoothing parameters are configured using a 3 × 3 kernel in the background subtraction stage and a 5 × 5 kernel in the foreground mask generation stage to reduce noise while preserving the boundaries of small moving objects. In addition, the hard threshold is lowered from 10% to 8% of the 8-bit grayscale range to improve sensitivity to weak motion.

To further improve detection quality, an optional shadow suppression step is added to reduce false positives caused by rapid lighting changes (Jacques et al., 2005). The resulting binary mask is then refined using a 3 × 3 median filter, morphological closing and opening with a 3 × 3 kernel, and blob filtering based on minimum and maximum area thresholds (St-Charles et al., 2015). After this refinement, candidate regions are extracted from the original frame for Stage 2 classification through a dynamic cropping mechanism. In this process, each detected blob is cropped using a bounding box expanded by 10% in all directions, padded to a square shape, and resized to the fixed input size to match the classifier.

b) Stage 2

Following Stage 1, Stage 2 aims to detect the presence of wasps within the regions represented by the extracted blobs using a classifier. As shown in Table 2, four state-of-the-art classification models designed for low-cost execution were compared for this purpose. Based on Table 2, latency alone cannot be considered a fair basis for comparison when the models are evaluated on different devices.

Table 2
Analysis of classification methods for stage 2

Model	Year	Accuracy	Dataset	Latency (ms)	FLOPs (G)	Parameters (M)	Device
RepViT-M1.0 (Wang et al., 2024)	2023	78.6	ImageNet-1K	1.0	1.1	6.8	iPhone 12
MNv4-Conv-M (Qin et al., 2024)	2024	79.9	ImageNet-1K	1.1	1.0	9.2	iPhone 13
GhostNetV3 (Liu et al., 2024a)	2024	77.1	ImageNet-1K	14.69	0.167	6.1	Huawei Mate 40 Pro
MobileOne-S1(Vasu et al., 2023)	2023	75.9	ImageNet-1K	0.89	0.825	4.8	iPhone 12

Differences in hardware and software configurations can significantly affect performance, and even newer versions from the same manufacturer may achieve lower latency due to hardware improvements. Therefore, directly comparing models tested on devices such as the iPhone 12, Huawei Mate 40 Pro, and iPhone 13 would not be reliable. To ensure a fairer evaluation, the comparison is limited to RepViT-M1.0 and MobileOne-S1, since both were tested on the iPhone 12. Based on the reported results, both models achieve latency below 1 ms and accuracy values of 78.6% and 75.9%, respectively, making them suitable for deployment in edge devices. Among them, MobileOne-S1 appears more suitable because it requires fewer FLOPs and has a smaller number of parameters than RepViT-M1.0. This indicates lower memory usage and reduces computational cost for the overall system, at the expense of only a small drop in accuracy of 2.7%. Given that the main objective of this stage is to classify objects using low computational power, this trade-off is acceptable. Moreover, even when evaluated on more advanced devices, MNv4-Conv-M and GhostNetV3 provide only a small accuracy improvement over MobileOne-S1 while introducing higher latency. Compared with MobileOne-S1, MNv4-Conv-M improves accuracy by 4.0%, while GhostNetV3 improves it by 1.2%. However, their latency increases from 0.89 ms to 1.1 ms and 14.69 ms, respectively despite the lower FLOPs recorded by GhostNetV3. In addition, both models have a higher parameter count than MobileOne-S1.

After selecting MobileOne-S1 for Stage 2, the model is adapted for three-class classification by replacing

the original ImageNet classification head with a new linear layer that outputs logits for bee, background, and wasp. The backbone structure is kept unchanged in order to preserve the model's efficiency for edge deployment. The model is then fine-tuned for 120 epochs using SGD with momentum 0.9 and an initial learning rate of 0.01, followed by cosine decay without restarts. To improve generalization, the fine-tuning process uses random resized cropping, horizontal flipping, random translation of up to 10% along both width and height, and Random Erasing with a probability of 0.25 over 2%–20% of the image area. Since wasp samples are less frequent than bee samples in nature at beehive entrance, class imbalance is addressed by combining cross-entropy with label smoothing of 0.1 and class-balanced weighting (Cui et al., 2019).

$$w_c = \frac{1-\beta}{1-\beta^{n_c}} \quad (1)$$

where β=*0.9998*, and the final loss is defined as,

$$\mathcal{L}_{CB}(z,y) = w_y \cdot \mathcal{L}_{CE}^{smooth}(z,y) \quad (2)$$

Model performance is monitored at the end of each epoch using both the standard and EMA-weighted versions, and fine-tuning is stopped when the validation loss does not improve for 10 consecutive epochs, with the checkpoint having the highest macro F1 score selected for testing and final deployment.

c) Stage 3

Following Stage 2, Stage 3 focuses on localizing wasps within the selected images that are likely to contain them. Given the limited availability of data, open-vocabulary detection models are considered for this stage, as they are trained on large-scale datasets compared to traditional CNN and Transformer models. It can support the detection of new object categories in the future without additional training. Therefore, such state-of-the-art models are analyzed for stage 3.

Based on analysis, DINO 1.5 Pro appears to be the most suitable model for this stage in terms of detection performance with mAP of 54.3 (Ren et al., 2024). However, its practical use is limited because the trained weights are not publicly available for download. The model's dependence on a commercial API makes offline deployment difficult and reduces its suitability for low-cost implementation. Among the models that are fully accessible, DINO Swin L achieves the closest performance to DINO 1.5 Pro with mAP of 52.5 (Liu et al., 2024b). It delivers the highest zero-shot accuracy among the models available for offline use and outperforms YOLO-World V2 X by approximately 5.4 mAP points (ultralytics, 2024). However, DINO Swin L is still a large transformer-based model, which may limit its applicability in edge devices. In contrast, YOLO-World V2 X is mainly based on the YOLO CNN architecture, which is generally more lightweight and computationally efficient. Therefore, although its detection accuracy is lower, it may provide a more practical balance between performance and deployment cost. Moreover, Vdoviak et al. (2025) show that YOLO-World V2 maintains low inference time and fast execution speed typical of YOLO-based models. This makes it a suitable candidate for the current task, with the added benefit of open-vocabulary detection. However, the results also suggest that the model would likely require fine-tuning to achieve better performance on a more specific target group, such as bees and wasps.

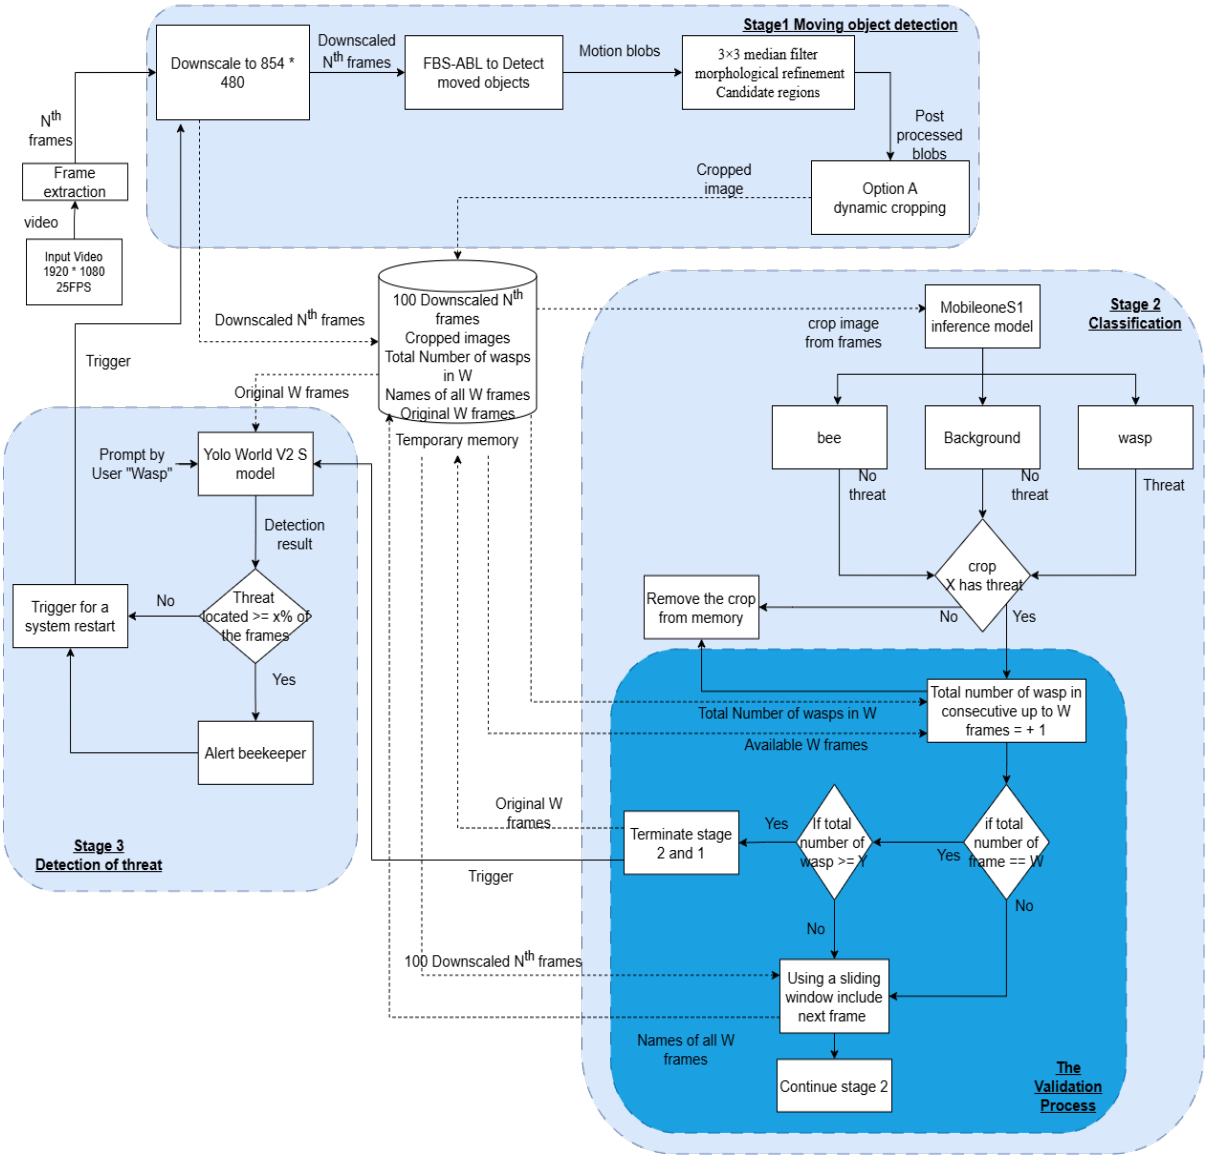
To adapt YOLO-World V2 for Stage 3, the model is adapted for wasp localization using prompt tuning in order to preserve its open-vocabulary capability for unseen classes. The backbone structure is kept unchanged, and the model is then fine-tuned for 30 epochs using Adam with momentum 0.9 and an initial learning rate of 0.01, followed by cosine decay without restarts. To improve generalization, the fine-tuning process uses horizontal and vertical translation of up to 10%, scaling of up to 0.5, and horizontal flipping. Unlike Vdoviak et al. (2025) multi-class setup, the current system focuses only on wasp detection. Therefore, only wasp instances are annotated during finetuning, while other objects such as bees, drones, and pollen-carrying bees are left unlabelled. In addition, negative images without wasps are included so that the model learns to better distinguish wasps from bees and background. Under this setup, the total loss function is defined as,

$$\text{TotalLoss} = \lambda_{box} BoxLoss + \lambda_{cls} ClsLoss + \lambda_{dfl} dflLoss \quad (3)$$

where $\lambda_{box} = 7.5$, $\lambda_{cls} = 0.5$, $\lambda_{dfl} = 1.5$.

Later while fine-tuning, Model performance is monitored at the end of each epoch using validation loss and AP50, and the checkpoint with the highest AP50 is selected for testing and final deployment.

d) Hardware



All model development, fine-tuning, and initial evaluation were carried out on a workstation with Windows 10, Visual Studio Code, an Intel Core i3-10100 CPU at 3.60 GHz, an NVIDIA GTX 1650 GPU, 24GB DDR4 RAM and Python as the implementation language. For edge deployment, the NVIDIA Jetson Nano was selected as the target device. It includes a quad-core ARM Cortex-A57 CPU, a 128-core Maxwell GPU, and 4 GB LPDDR4 shared memory. This device was chosen as edge device because it provides a low-cost platform for vision-based AI tasks while supporting both CPU-based and GPU-accelerated processing, which suits the proposed multi-stage pipeline.

e) Dataset

After customizing the models, the dataset was required to satisfy three main conditions. First, it had to contain images of both wasps and bees. Second, it had to be taken using different background settings to increase generalization. Finaly, it had to include consecutive frames with only a small time interval, since Stage 1 relied on FBS-ABL, whose performance is strongly

influenced by the temporal gap between frames. For this reason, Sledevič & Vdoviak (2025) were selected as the dataset for fine-tuning and testing. It was distributed under the CC BY 4.0 license and contained 11,008 images with YOLO-format annotations, including 116,853 worker bees, 14,062 pollen instances, 1,405 wasps, and 1,320 drones. However, since the dataset was not originally created for the specific task addressed in this study, it was manually filtered before use, as a considerable portion of the data contained larger time intervals between consecutive frames. As a result, a sub-dataset satisfying these requirements was generated and published at Manivannan (2026).

Figure 1
Architecture of the system (Kirishanth, 2026)

Results and Discussion

a) System architecture

Following the selection and customization of the models and the preparation of the dataset, the three stages are integrated into a one-tier architecture that can be executed on NVIDIA Jetson Nano. This enables the system to operate independently without relying on remote hardware for additional computational resources. The architecture consists of two main components: a low-power monitor and a high-power verifier. The low-power monitor, which includes Stages 1 and 2, operates continuously to detect possible wasp presence. When Stage 2 identifies a possible wasp, the high-power verifier is triggered to localize the threat within the image. To allocate sufficient computational resources for this process, the low-power monitor will be temporarily suspended while the high-power verifier performs localization. Furthermore, the complete architecture of the proposed system is presented in Figure 1 and is described as follows.

As illustrated in Figure 1, the input video is recorded at 1920×1080 pixels to preserve detailed visual

information at the hive entrance. Then every N^{th} frame is downscaled to 854×480 pixels for further processing in order to lower computational cost while preserving the original 16:9 aspect ratio. In Stage 1, FBS-ABL processes consecutive frames to identify motion regions at the hive entrance. After post-processing of these motion regions, candidate blobs are converted into cropped regions that are stored together with the corresponding recent frames in temporary memory. To limit memory usage, only the most recent 100 frames are stored. These cropped regions are then passed to Stage 2, where MobileOne-S1 classifies them as a bee, background, or a wasp.

Stage 2 acts as a lightweight verification layer before the more computationally expensive localization Stage 3 is activated. Analysis of the dataset showed that when a wasp appears, it is usually visible across multiple consecutive frames rather than in a single isolated frame. For this reason, the system does not rely on a single wasp prediction. Instead, when wasp predictions are detected, they are evaluated over a sliding window of 20 frames. If the total number of wasp predictions within the window reaches the threshold of 8, Stages 1 and 2 are suspended and Stage 3 is triggered. Otherwise, the window continues to advance until either the threshold is reached or no wasp predictions remain within the current 20-frame window. In that case, the validation process is cleared and returns to an idle state until the next wasp prediction is observed. This validation step helps reduce unnecessary activation of Stage 3 by requiring repeated evidence of wasp presence within a limited sequence of frames, thereby lowering the likelihood of false triggers. Moreover, since Stages 1 and 2 are temporarily suspended while Stage 3 is running, the system may, in rare cases, miss true wasp appearances during this interval. Then, to prevent unnecessary memory growth during this stage, the cropped regions are permanently removed from memory after classification, while only the running wasp count and the frame identifiers for the current window are retained. Once triggered, Stage 3 retrieves the corresponding full 20 frames from temporary memory and applies YOLO-World V2 S to localize wasps. If detections are confirmed in at least 60% of the selected frames, the system generates an alert for the beekeeper by uploading the images to the cloud and informing through email using RCLONE and MSMTP General Commands Manual. After that, the monitoring cycle is restarted and clears the temporary memory. This staged design reduces the amount of data processed by the most computationally demanding model, since only a small subset of frames reaches the final detection stage. As a result, the architecture supports efficient operation on low-cost Jetson Nano while maintaining the ability to detect and localize wasp threats in real time.

b) Results in Workstation

For Stage 1, the experiments focused on how the temporal gap between frames and the background update settings influence the performance of FBS-ABL. First, the number of frames used to initialize the background model was increased from 1 to 50 while keeping the background update interval fixed. This analysis was performed on two collections with different temporal gaps between consecutive frames in order to observe how frame interval influences motion extraction. The results showed that shorter frame intervals produced more stable behavior and higher precision, whereas larger frame intervals resulted in slightly higher recall but lower precision and greater fluctuation due to the increased temporal variation between consecutive background frames. In the low-interval collection, precision became largely stable after around 27 frames, while recall decrease as additional frames were included to initialize the background model. Therefore, 27 frames were selected for background model initialization, as this provided a suitable balance between the precision and recall. And since lower precision would increase the number of background crops passed to Stage 2, low-interval frame data were considered more suitable for the proposed system. In the second experiment, the interval for updating the background model was increased while the initial background model size was fixed at 27 frames. The results showed that a longer update interval caused only a small reduction in precision, while recall remained almost unchanged. However, a shorter update interval required more computational power due to more frequent background model updates. Therefore, an update interval of 30 frames was selected as a balance between real-time processing speed and accuracy.

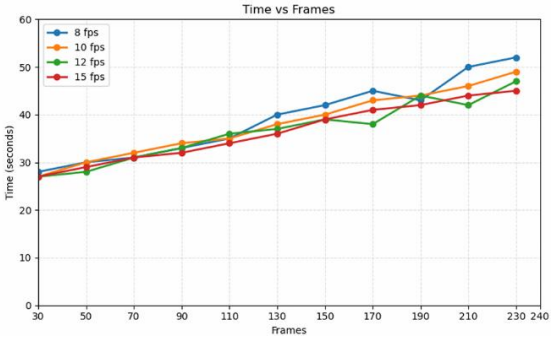
For Stage 2, MobileOne-S1 was fine-tuned using 2,481 bee crops, 693 background crops, and 848 wasp crops represents the outputs of stage 1. The dataset was divided into fine-tuning and validation sets using an 80:20 ratio, while Collections 3 and 19 were reserved for testing in order to better reflect deployment conditions. During fine-tuning, both the standard and EMA-weighted models showed stable learning behavior, with the validation macro F1 score improving rapidly in the early epochs and then gradually stabilizing. A temporary drop in performance was observed around epoch 40, which aligned with the progressive learning step that increased the input resolution from 32 × 32 pixels to 48 × 48 pixels. Although this transition briefly affected performance, the model recovered and continued to improve. Since the EMA-weighted model showed more stable behavior toward the later epochs, the checkpoint with the best EMA macro F1 score was selected as the final Stage 2 model. On the test set, the selected model achieved a loss of 0.24 and a macro F1 score of 0.8941. The per-class F1 scores were 0.9422 for background, 0.9692 for bee, and 0.7708 for wasp.

The lower wasp score can be attributed partly to the smaller number of wasp samples available during fine-tuning, which restricts the diversity of features the model can learn for that class. Furthermore, wasps

share several visual similarities with bees, which may have increased the difficulty of reliable separation. Although the test macro F1 score of 0.8941 was lower than the best validation macro F1 score of approximately 0.95, the gap remained moderate and suggested only limited overfitting, which could likely be reduced by adding more diverse wasp data. In particular, the fine-tuning and validation losses decreased together and remained close, indicating stable convergence without clear signs of strong overfitting or underfitting, although the lower test performance on the wasp class suggested limited difficulty in generalization to unseen data.

For Stage 3, YOLO-World V2 S was fine-tuned for single-class wasp detection using 639 annotated frames containing wasps and 135 negative frames without wasps. The negative frames were included to improve separation between wasps, bees, and background under the single-class detection setup. The dataset was divided into fine-tuning and validation sets using 80:20 ratio, while Collections 3 and 19 were reserved for testing in order to better reflect deployment conditions.

During fine-tuning, the model showed rapid early improvement, with mAP50 increasing sharply in the first few epochs as the model learned the most obvious visual patterns of the target class. The curve then gradually stabilized, indicating that the model had learned most of the useful features available in the fine-tuning data. Minor fluctuations between epochs were likely caused by data augmentation and the relatively small dataset size. Similar to Stage 2, the fine-tuning and validation losses decreased together and remained close, indicating stable convergence without clear signs of strong overfitting or underfitting. However, unlike Stage 2, the validation and test performances in Stage 3 remained highly consistent. On the validation set, the model reached an mAP50 of 0.956, and the precision–recall curve remained close to the upper boundary across most confidence thresholds, indicating high precision over a wide range of recall values. On the test set of 193 images, the model achieved an mAP50 of 0.9566.

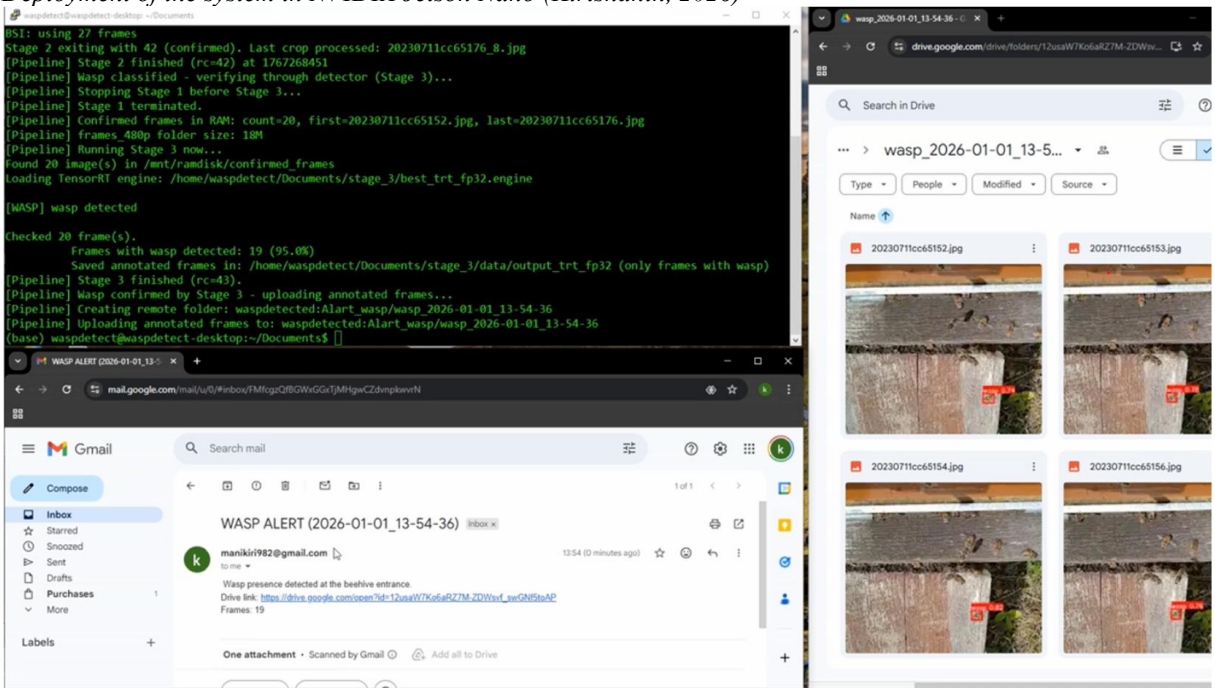


c) Results in NVIDIA Jetson Nano

After the individual stages were evaluated on the workstation, the complete pipeline was deployed on the NVIDIA Jetson Nano to assess its suitability for low-cost edge execution. On Jetson Nano, Stage 1 achieved 21.767 FPS, compared with 84.187 FPS on the workstation. Although this reduction was expected because of the Jetson Nano's lower processing capability and limited power budget of maximum 15W, the measured speed remained sufficient for the intended low-interval input setting. For Stage 2, the re-parameterized MobileOne-S1 deploy model achieved 108.5 FPS in FP32, while conversion to a TensorRT FP16 module increased the speed to 168.84 FPS with essentially unchanged accuracy and macro F1 score. For this reason, the FP16 version was selected for deployment. In Stage 3, YOLO-World V2 S was exported to ONNX on the workstation and compiled into a TensorRT engine on the Jetson Nano to avoid software compatibility issues in the device runtime environment. The YOLO-World V2 S detector achieved 4.07 FPS on the Jetson Nano, compared with 52.84 FPS on the workstation. Although this stage was substantially slower, it was considered acceptable because Stage 3 is activated only when Stage 2 indicates possible wasp presence, and during its execution the state 1 and 2 are suspended so that the detector can use the full device resources.

The fully integrated system was then evaluated using input streams configured to mimic a 10 FPS deployment setting. The results showed a fixed one-time startup delay of approximately 27s. This delay was mainly caused by initialization overhead on the Jetson Nano, including the 27 frames required by Stage 1 to initialize the background model and the one-time JIT compilation cost introduced by the Numba-accelerated functions. Although a warm-up phase was introduced in Stage 2 to reduce GPU startup overhead, the initial delay could not be removed entirely since Stage 2 depends on the outputs of Stage 1. After initialization, the total runtime increased approximately linearly with the number of frames across tested input rates between 8 and 15 FPS as in Figure 2, indicating stable and predictable per-frame processing cost. This behavior suggests that the deployed system can support near live surveillance within the tested range, despite the constant initialization delay.

Figure 2



Runtime in Jetson Nano at Deployment for 8,10,12 and 15 FPS input frame rate (Kirishanth, 2026)

Following the successful evaluation of the system, Figure 3 presents an example of the final alert output. In this case, after the trigger condition was satisfied in Stage 2, Stage 3 was activated and confirmed wasp presence in 19 of the 20 selected frames, which exceeded the 60% decision threshold. The system then produced the final alert by uploading them to cloud storage, and sending an email notification to the beekeeper, which demonstrates the successful end-to-end operation of the deployed system on the Jetson Nano.

Figure 3

Deployment of the system in NVIDIA Jetson Nano (Kirishanth, 2026)

Conclusions

1. The wasp detection problem was successfully divided into three stages: motion-based candidate extraction, lightweight classification, and final verification with localization, allowing the system to function with limited computational resources.
2. FBS-ABL, MobileOne-S1, and YOLO-World V2-S were identified as the most suitable models for Stages 1, 2, and 3, based on the requirements of each stage.
3. The proposed one-tier, three-stage architecture enabled continuous low-cost monitoring through Stages 1 and 2, while Stage 3 was activated only after preliminary verification to reduce unnecessary computational load and false alarms.
4. The complete system was successfully deployed on the Jetson Nano and achieved near real-time wasp surveillance, with an initialization delay of approximately 27s across input rates of 8, 10, 12, and 15 FPS.
5. Future improvements should focus on reducing the initialization delay, expanding the dataset with more diverse wasp samples, evaluating the system under a wider range of real-world operating conditions and similar problems.

Abstract
Artificial intelligence (AI) is increasingly embedded in organizational processes, reshaping work structures, task composition, and competence requirements. While existing literature has extensively examined AI's macro-level labour market implications, less attention has been devoted to the organizational mechanisms through which AI influences human capital development in territorially differentiated contexts, particularly in smaller economies and rural and lower-density environments. Specifically, limited research has examined how AI-driven human capital transformation unfolds in small and territorially differentiated economies, where digital infrastructure and institutional support systems vary significantly. This exploratory study examines how AI integration is perceived to affect work processes and skill demands among employees in Latvian organizations and outlines structural conditions that may enable or constrain sustainable human capital transformation in territorially differentiated, rural, and lower-density contexts. The research combines theoretical analysis with empirical survey data collected from 61 employees across Latvian organizations. Within the surveyed sample, responses tend to associate AI adoption primarily with task restructuring and rising competence requirements rather than with direct workforce reduction. The observed response patterns are consistent with the view that human capital development outcomes may depend on organizational capability structures, training institutionalization, and change management practices. The results are interpreted within a territorially differentiated analytical framework, proposed conceptually rather than tested empirically, which raises the question whether in rural and lower-density contexts AI integration may remain primarily efficiency-oriented unless supported by systemic learning mechanisms. The study contributes to the understanding of AI as a capability-dependent transformation process and highlights the necessity of embedding territorial and regional development perspectives within analyses of AI-driven workforce transformation.
Keywords: artificial intelligence, human capital, territorial differentiation, rural and regional development, organizational transformation.

Introduction

Artificial intelligence (AI) has evolved from a specialized technological application into a broader transformation force within contemporary organizations (Brynjolfsson & McAfee, 2014; Agrawal et al., 2019). Unlike earlier digital technologies that primarily enhanced information processing efficiency, AI systems increasingly perform cognitive, predictive, and decision-support functions (Davenport & Ronanki, 2018). As a result, AI integration alters not only productivity levels but also the qualitative structure of work, redistributing tasks between human and algorithmic agents. Artificial intelligence can be conceptualized as a general-purpose technology (GPT), characterized by broad applicability, continuous improvement, and complementarities with organizational and institutional structures. General-purpose technologies generate systemic transformation effects that extend beyond direct productivity gains, reshaping complementary assets, skill structures, and innovation trajectories (Bresnahan & Trajtenberg, 1995). Recent macroeconomic research further suggests that the productivity effects of such technologies may follow a delayed 'J-curve' pattern, as organizational restructuring and intangible investments are required before performance gains materialize (Brynjolfsson et al., 2021). In this sense, AI-driven transformation cannot be reduced to automation effects alone; it represents a structural reconfiguration of production and coordination systems.

The academic debate has largely focused on automation risks and macroeconomic labor displacement (Autor, 2015; Acemoglu & Restrepo, 2019). However, the transformation of human capital at the organizational level remains less systematically examined, particularly in smaller and regionally differentiated economies. The assumption that AI adoption produces homogeneous effects across contexts neglects the structural role of organizational capacity, institutional environment, and territorial characteristics. From a digital transformation perspective, technological adoption constitutes a multi-layered organizational change process affecting strategy, structure, routines, and value creation mechanisms (Vial, 2019). AI integration therefore interacts with existing organizational capabilities and institutional contexts, producing heterogeneous outcomes across firms and regions.

From a human capital theory perspective (Becker, 1964), skills constitute a productive asset whose value depends on alignment with technological and organizational demands. Under AI-driven transformation, human capital cannot be understood as a static stock of qualifications. Instead, it represents a dynamic capability requiring continuous adaptation, reskilling, and learning integration.

This issue is particularly salient in territorially differentiated environments, where infrastructural density, access to digital expertise, and institutional support systems may vary, potentially producing uneven AI adoption trajectories across regions, including rural and lower-density contexts (Rodríguez-Pose, 2013). For this reason, the present study situates AI-related human capital transformation within a rural and regional development perspective. The aim of this

study is to explore how artificial intelligence integration is perceived to affect work processes and competence requirements in Latvian organizations and to identify organizational mechanisms that may enable sustainable human capital development under conditions of technological change.

The research question is:

What challenges do employees report when using artificial intelligence in their daily work, and which organizational mechanisms are perceived to facilitate sustainable human capital development in territorially differentiated contexts?

The survey instrument did not include regional identifiers; direct rural-urban comparison is therefore outside the scope of this exploratory stage. Accordingly, the territorial dimension is used here as an interpretive framework for situating the findings within broader rural and lower-density development contexts.

By situating AI within an organizational and regional development framework, the study contributes to a more context-sensitive understanding of technology-driven workforce transformation. Given the relatively limited organization-level empirical evidence on AI-driven human capital transformation in small and territorially differentiated economies, this study adopts an exploratory research design. The objective is to identify tentative patterns and generate hypotheses for subsequent confirmatory research, interpreted within a capability-based framework attentive to territorially differentiated and rural and lower-density contexts.

AI-Driven Organizational Transformation and Human Capital Reconfiguration

Artificial intelligence (AI) represents not merely a technological advancement but a structural transformation of organizational systems. Unlike earlier waves of digitalization that primarily enhanced information processing efficiency, AI increasingly performs predictive, analytical, and decision-support functions traditionally associated with human cognitive labor (Brynjolfsson & McAfee, 2014; Davenport & Ronanki, 2018). As a result, AI integration reshapes not only productivity levels but the qualitative architecture of work itself, redistributing tasks between human and algorithmic agents and altering competence requirements across organizational levels.

From a labor economics perspective, task-based models of technological change suggest that technologies affect discrete task components rather than eliminating occupations in their entirety (Autor, 2015; Acemoglu & Restrepo, 2019). AI systems particularly automate routine, codifiable, and data-intensive activities, thereby increasing the relative importance of non-routine analytical, interpretative, and integrative tasks (Agrawal et al., 2019). This redistribution aligns with augmentation-oriented interpretations, which emphasize that AI creates organizational value when complementing human judgment rather than substituting it (Brynjolfsson, 2022). In this context, the central issue is not job replacement but task reconfiguration and competence intensification. Recent management research conceptualizes this dynamic as the automation-augmentation paradox, whereby AI simultaneously substitutes specific tasks while amplifying the strategic importance of human judgment and integrative capabilities (Raisch & Krakowski, 2021). Rather than a binary automation outcome, organizations experience hybrid configurations in which algorithmic systems execute analytical components while humans retain interpretative, ethical, and contextual decision authority.

However, AI-driven transformation extends beyond task restructuring. Empirical research indicates that algorithmic systems embedded in workflow coordination and performance monitoring may alter autonomy structures and decision-making authority within organizations (Kellogg et al., 2020). While AI can enhance decision accuracy and efficiency, excessive reliance on algorithmic outputs may reduce discretionary space and reshape professional identity. The expansion of algorithmic management further illustrates this transformation. Empirical studies indicate that data-driven coordination systems alter control mechanisms, transparency, and performance evaluation structures within organizations (Lee et al., 2015). Algorithmic monitoring can increase efficiency and standardization, yet it may also intensify perceived surveillance and reduce discretionary autonomy (Newlands, 2021). These governance shifts influence not only productivity but also employee motivation and organizational trust. Studies further associate AI integration with increased performance expectations and technostress, particularly when reskilling mechanisms are insufficient (Tarafdar et al., 2007; Ayyagari et al., 2011). These findings suggest that AI adoption introduces both productivity gains and psychological pressures, making organizational mediation mechanisms critical.

The socio-technical systems perspective provides a conceptual lens for understanding this mediation. Technological effectiveness depends on alignment between technical infrastructure and social organization (Trist & Bamforth, 1951; Cherns, 1976). AI implementation therefore requires coordinated adjustments in work design, governance structures, and learning systems. Where technological deployment outpaces organizational adaptation, misalignment may generate skill mismatches, uncertainty, and resistance. Conversely, transparent governance frameworks and institutionalized training support can convert AI adoption into a catalyst for sustainable capability development. Human-AI collaboration literature further suggests that effective integration depends on designing complementary interaction architectures rather than pursuing maximal automation. Jarrahi (2018) argues that AI systems enhance decision-making quality when embedded within socio-technical arrangements that preserve

human interpretative authority. Accordingly, governance frameworks that clarify accountability, transparency, and learning feedback loops are critical for sustainable organizational adaptation.

These dynamics fundamentally challenge classical interpretations of human capital. Traditionally conceptualized as a relatively stable accumulation of knowledge and skills generating economic returns (Becker, 1964), human capital under AI-driven transformation becomes temporally compressed and continuously reconfigured. As routine cognitive functions are increasingly automated, the relative value of creativity, contextual reasoning, critical thinking, and cross-functional coordination intensifies (Autor, 2015; Brynjolfsson, 2022). Human capital thus shifts from a static stock of qualifications toward a dynamic organizational capability.

From a capability-based perspective (Teece, 1997), sustainable adaptation to AI integration depends on an organization's capacity to sense technological shifts, seize opportunities through structured competence development, and transform internal processes accordingly. Human capital development under AI is therefore not an automatic consequence of technological adoption; it emerges through deliberate institutionalization of learning architectures, knowledge transfer mechanisms, and change management practices. Knowledge transfer literature emphasizes that absorptive capacity conditions the effectiveness of technological integration (Cohen & Levinthal, 1990). Empirical and conceptual research in the Latvian context similarly identifies structural knowledge transfer gaps as barriers to organizational capability upgrading, particularly in regionally embedded enterprises (Ozoliņa-Ugore et al., 2025). In AI-intensive environments, such constraints may slow adaptation and intensify divergence between digitally mature and lagging organizations.

Importantly, AI-driven organizational transformation unfolds within territorially differentiated environments. Technological adoption capacity is mediated by infrastructural density, institutional support systems, and access to specialized knowledge networks. Regional development research indicates that innovation and digital maturity levels are unevenly distributed across spatial contexts (OECD, 2019). In Latvia, national strategic documents emphasize artificial intelligence adoption and digital competence upgrading as critical pillars of long-term competitiveness (Ministry of Environmental Protection and Regional Development, 2020). However, the translation of strategic priorities into organizational capability development depends on firm-level absorptive capacity and regional institutional ecosystems, suggesting potential implementation asymmetries across territories. Nevertheless, European Commission DESI reports indicate persistent disparities in digital maturity across regions (European Commission, 2023). Such structural asymmetries are particularly salient in rural and lower-density contexts, where enterprises may face constraints in accessing advanced digital expertise and continuous professional development ecosystems.

Empirical evidence from the Latvian FinTech sector indicates that AI-based tools influence not only operational efficiency but also trust formation and behavioural adaptation among users (Meldere & Andersone, 2025). These findings align with international research emphasizing that AI transformation extends beyond internal productivity effects toward broader relational and institutional dimensions (Pentjuša & Gaile-Sarkane, 2025). These findings are consistent with broader organizational behaviour research demonstrating that autonomy enhances intrinsic motivation and engagement under technologically mediated work conditions (Hackman & Oldham, 1976; Pentjuša & Gaile-Sarkane, 2025). In AI-supported environments, autonomy may function as a buffering mechanism against potential perceptions of algorithmic control. These findings are consistent with the argument that AI transformation is relational and systemic rather than purely technical.

Taken together, AI-driven organizational transformation operates across multiple interrelated levels. At the micro level, AI restructures task composition and intensifies competence requirements. At the organizational level, outcomes depend on governance alignment, structured learning systems, and knowledge transfer capacity. At the territorial level, infrastructural and institutional conditions mediate the depth and trajectory of capability reconfiguration. Human capital development under AI should therefore be understood as a dynamic, territorially embedded process emerging from the interaction between technological systems, organizational adaptation mechanisms, and spatial development conditions.

Ontological aspects of human capital in the context of AI

The expansion of artificial intelligence challenges classical ontologies of human capital by destabilizing the assumption that formal education and accumulated qualifications constitute relatively stable productivity assets (Becker, 1964).

In AI-integrated work environments, human capital increasingly encompasses adaptive learning capacity, digital literacy, critical interpretation of algorithmic outputs, and cross-functional coordination skills. As routine cognitive activities become automated, the relative value of non-codifiable competencies, such as creativity, contextual reasoning, and social intelligence, intensifies (Autor, 2015; Brynjolfsson, 2022). This shift aligns with skill-biased technological change theory, which predicts rising demand for higher-order cognitive capabilities alongside declining reliance on routine functions.

Importantly, the transformation of human capital is not solely cognitive but also organizational and psychological. Empirical research links AI integration to heightened performance expectations, technostress,

and perceived job insecurity, particularly when reskilling support is insufficient (Tarafdar et al., 2007; Ayyagari et al., 2011). Technostress research provides additional explanatory depth to this phenomenon. Empirical studies identify techno-overload, techno-invasion, and techno-complexity as structural stressors associated with advanced information systems (Tarafdar et al., 2007). Subsequent research suggests that rapid technological change may increase role ambiguity and cognitive strain, particularly when organizational support mechanisms are weak (Ayyagari et al., 2011). Within AI-intensive environments, these stressors may be amplified by perceived algorithmic opacity and performance monitoring intensity.

These findings suggest that human capital development cannot be reduced to skill acquisition alone; it must include structured change management processes that support sense-making and participation (Lewin, 1947; Kotter, 1996).

Beyond structural adaptation, the ontological status of human capital itself undergoes transformation. In AI-integrated environments, employees are no longer valued primarily for the possession of stable, task-specific qualifications, but for their capacity to interpret, contextualize, and critically engage with algorithmic systems. This shift represents an epistemic reorientation in which knowledge is increasingly co-produced through human-machine interaction rather than individually accumulated. Professional identity consequently evolves from task executor to system interpreter and adaptive coordinator. Human capital thus becomes relational and processual, constituted through continuous interaction with technological infrastructures rather than defined solely by pre-existing competencies. This reconceptualization aligns with organizational learning theory, which views knowledge as socially constructed and continuously reconfigured through interaction (Argyris & Schön, 1978). In technologically dynamic contexts, double-loop learning mechanisms become particularly important, enabling organizations not only to refine routines but to question underlying assumptions regarding task allocation and decision authority. The knowledge-based view of the firm further supports this interpretation, emphasizing that competitive advantage derives from the integration and transformation of distributed knowledge assets (Nonaka & Takeuchi, 1995). Under AI integration, human capital thus becomes embedded within collective learning processes rather than residing solely at the individual level.

Accordingly, human capital in AI-driven environments should be conceptualized as a dynamic, relational capability rather than a static accumulation of qualifications. Organizations that institutionalize continuous learning, transparent technological governance, and participatory adaptation mechanisms appear better positioned to transform AI integration into sustainable workforce development rather than episodic efficiency gains.

Knowledge transfer limitations further illustrate that human capital is not merely accumulated but socially mediated. Gaps between knowledge creation and effective organizational absorption can constrain adaptive capacity, particularly in technologically dynamic environments (Ozoliņa-Ugore et al., 2025). In AI-integrated contexts, insufficient absorptive structures may delay identity transformation and competence consolidation.

Building on the preceding discussion, the empirical component focuses on three interrelated dimensions identified in the literature: the perceived intensity of AI integration in daily work, the reconfiguration of task composition and competence demands, and the organizational mechanisms that mediate human capital outcomes. These dimensions frame both the questionnaire design and the structure of the analysis presented below. They are also relevant to rural and regional development debates, since the capacity to support skill adaptation may vary across territorially differentiated and rural and lower-density contexts.

Materials and Methods

The study is designed as an exploratory empirical investigation aimed at examining how artificial intelligence integration reshapes work processes and competence requirements within Latvian organizations. Given the relatively limited organization-level evidence on AI-driven human capital transformation in small and regionally differentiated economies, the research does not seek to test predefined causal hypotheses. Rather, it aims to identify structural patterns in employees' experiences and interpret these patterns through the theoretical lens of task reconfiguration and capability adaptation.

Empirical data were collected through an anonymous online questionnaire distributed via professional networks and organizational contacts across Latvia. Participation was voluntary. The final dataset consists of 61 respondents employed in organizations of varying size and sectoral orientation. The sample is sectorally diverse. The largest proportion of respondents represented the IT and technology sector (24.6%), followed by education (18.0%), finance and insurance (9.8%), public services (8.2%), with remaining sectors represented in smaller proportions.

In terms of demographic structure, 83.6% of respondents were female and 14.8% male. The dominant age group was 35-44 years (47.5%), followed by 45-54 years (32.8%), indicating that the sample primarily reflects mid-career professionals with substantial organizational experience. Although the sampling approach was non-probabilistic and based on accessibility, it enabled access to employees actively engaged in digitally supported work environments. Given the exploratory design of the study and its focus on identifying structural tendencies rather than statistically generalizable causal relationships, the sample size of 61 respondents is

methodologically aligned with the research objective. In this sense, the sample is analytically appropriate for examining AI-related workplace dynamics, even if it does not allow for statistical generalization to the entire Latvian labor market.

The questionnaire was constructed to capture three interconnected dimensions of AI integration: (1) the presence and intensity of AI usage in daily work; (2) perceived changes in task structure and work efficiency; and (3) shifts in competence requirements and organizational support mechanisms. AI impact was assessed using a ten-point evaluation scale, allowing respondents to indicate perceived intensity of influence on their daily tasks. Additional items examined whether AI use was associated with increased efficiency, altered decision-making processes, new skill acquisition demands, or reduced reliance on manual procedures. Open-ended questions invited respondents to describe organizational challenges and to propose measures that could facilitate more effective AI integration.

The analytical strategy combined descriptive statistical analysis with structured interpretation of thematic tendencies emerging from open-ended responses. Given the exploratory nature of the study and the moderate sample size, emphasis was placed on identifying distributional patterns, variance tendencies, and recurring interpretative themes rather than on inferential statistical modeling. The analysis therefore seeks to illuminate mechanisms of perceived task restructuring and competence intensification rather than to establish statistically predictive relationships. Given the exploratory design and the moderate sample size, inferential statistical modelling was not pursued. Instead, the analysis focuses on frequency distributions, response dispersion, and thematic patterns from open-ended answers. This choice aligns with the study's aim of generating hypotheses for subsequent confirmatory research rather than testing causal relationships. Accordingly, the reported findings should be read as indicative tendencies within the sample, not as generalizable estimates.

The survey did not include regional identifiers or formal rural-urban stratification variables. This is an explicit scope decision: the present study serves as a conceptual and exploratory first stage, designed to identify patterns relevant to broader rural and regional development debates, while spatially stratified empirical testing is reserved for a follow-up study. However, respondents were recruited through professional and organizational networks spanning multiple Latvian sectors. Territorial differentiation was not empirically measured through regional identifiers in the survey instrument. Consequently, territorial effects are interpreted analytically rather than statistically tested. Future research should explicitly include regional identifiers to enable empirical comparison of spatially differentiated AI integration patterns. Latvia's regional structure, characterized by uneven infrastructural density and digital maturity levels, provides a contextual framework within which heterogeneity in AI integration depth can be understood. The study thus incorporates territorial considerations analytically rather than through formal comparative segmentation.

Several limitations should be acknowledged. The sample size restricts representativeness, and the convenience-based recruitment strategy may favor respondents already exposed to digital technologies. The gender distribution of the sample is skewed toward female respondents (83.6%), which may reflect sectoral composition and should be considered when interpreting generalizability. Furthermore, the reliance on self-reported perceptions captures subjective evaluations rather than objective productivity indicators or independently measured skill acquisition outcomes. The empirical findings should therefore be interpreted as indicative patterns within a digitally engaged segment of Latvian employees rather than as generalizable estimates for the national workforce. Social desirability effects and self-selection into the survey may further shape reported perceptions of AI. Nevertheless, the study offers analytically relevant insight into organizational AI integration patterns in a small and regionally differentiated economy, contributing exploratory evidence to an area where systematic empirical research remains limited.

Results and Discussion

Within the surveyed sample, artificial intelligence appears to be embedded in daily work practices: 82.0% of respondents reported AI use in their workplace; 16.4% indicated no use, and 1.6% reported uncertainty. However, the data simultaneously indicate heterogeneity in perception and integration depth. A small proportion of respondents indicated uncertainty regarding whether AI is used in their workplace, suggesting that algorithmic systems are often embedded in digital tools without being explicitly recognized as 'artificial intelligence'. This finding reflects the normalization of AI functionalities within routine organizational infrastructures.

In total, 55.7% of respondents rated the impact as high on the 7-10 range, whereas 18.0% rated it as low on the 1-3 range, indicating substantial variation in integration intensity across organizations. Rather than demonstrating uniform transformation, the results suggest the existence of differentiated integration profiles. In some organizations, AI constitutes a structurally transformative element of work architecture; in others, its influence remains limited or functionally supportive. This pattern aligns with task-based theories of technological change, which emphasize that technologies restructure task composition incrementally rather than producing homogeneous or immediate occupational disruption (Autor, 2015; Acemoglu & Restrepo, 2019).

In line with this, 82.0% agreed that AI can improve employee efficiency, while 14.8% were unsure and

3.3% perceived a rather negative effect. This dual effect, combining efficiency enhancement with skill intensification, supports augmentation-oriented interpretations of AI adoption (Brynjolfsson, 2022). Within the sample, responses tend to portray AI as a complement to human labour rather than as a direct substitute. This tendency is consistent with augmentation-oriented interpretations in the literature, although confirmation would require broader, sectorally stratified, and spatially differentiated evidence. The relatively limited emphasis on workforce reduction or decreased human resource necessity is also consistent with this interpretation.

At the same time, the reported necessity to acquire new skills highlights the dynamic reconfiguration of human capital under AI integration. Employees experience rising expectations regarding digital literacy, analytical capability, and adaptive competence. These findings are consistent with skill-biased technological change perspectives, which predict increased demand for higher-order cognitive capabilities in technologically intensive environments (Autor, 2015). The responses are consistent with the proposition that human capital transformation is structurally embedded within AI adoption processes, although the exploratory design does not allow this claim to be tested causally.

Interestingly, negative responses related to decreased motivation or deteriorating work experience were marginal. While international research frequently emphasizes technostress and psychological strain associated with algorithmic monitoring (Tarafdar et al., 2007; Ayyagari et al., 2011), the present sample predominantly associates AI with functional improvements rather than emotional decline. This does not negate the existence of technostress but suggests that in the examined organizations, AI is currently perceived more as a productivity-enhancing tool than as a surveillance mechanism. It may also indicate that AI integration in this context has not yet reached levels of algorithmic control intensity observed in other sectors internationally.

Open-ended responses provide further insight into mediating organizational mechanisms. The most frequently mentioned support measures include: (1) clearer principles for AI usage, (2) practical and accessible training opportunities, and (3) transparent internal communication regarding implementation objectives. These responses reveal that the primary challenge is not technological complexity per se, but organizational alignment. This finding strongly resonates with socio-technical systems theory, which emphasizes that technological effectiveness depends on alignment between technical systems and social structures (Trist & Bamforth, 1951; Cherns, 1976). Where governance frameworks and communication channels are insufficiently structured, AI integration may remain partial or generate uncertainty.

From a capability-based perspective (Teece, 1997), these responses are consistent with the view that the depth of AI-driven transformation may depend on the institutionalization of learning mechanisms and structured change management practices. The survey responses are consistent with the view that organizations providing systematic training and clarifying AI governance may be better positioned to convert technological adoption into sustainable human capital upgrading. Conversely, where AI introduction lacks formalized support systems, employees may experience rising skill pressure without adequate institutional scaffolding.

The dispersion of impact evaluations further indicates that AI-driven transformation is neither linear nor uniform. At the national level, respondents most often evaluated Latvia's labor-market adaptation to AI as moderate at 49.2%, followed by positive evaluations at 21.3%, negative evaluations at 13.1%, and uncertainty at 16.4%. Some respondents report substantial improvements in work quality and task efficiency, while others perceive only marginal change. This heterogeneity may reflect differences in organizational maturity, digital infrastructure, leadership engagement, and absorptive capacity. In line with knowledge transfer research in the Latvian context (Ozoliņa-Ugore et al., 2025), the effectiveness of technological integration appears closely linked to the strength of internal knowledge diffusion mechanisms.

Although the study did not explicitly stratify respondents by territorial location, the observed variability in AI integration depth has implications for regionally differentiated environments. This limitation suggests that future research should incorporate territorial segmentation to empirically test whether regional digital maturity levels correlate with differences in perceived AI impact and competence upgrading intensity. A plausible hypothesis, to be examined in subsequent regionally and spatially segmented research, is that in rural and lower-density organizational contexts limited access to specialized AI expertise, advanced digital infrastructure, and continuous professional development ecosystems may constrain the depth of transformation, leaving AI adoption predominantly operational rather than strategic. The present data do not allow this hypothesis to be tested directly. This interpretation aligns with broader regional development research demonstrating that digital maturity and innovation capacity are unevenly distributed spatially (OECD, 2019; European Commission, 2023).

Contemporary regional economics further indicates that technological upgrading is closely linked to smart specialization strategies and regional innovation ecosystems (McCann & Ortega-Argilés, 2015). Regions characterized by dense institutional collaboration and diversified knowledge bases are better positioned to internalize digital transformation benefits. Conversely, structurally weaker regions may experience cumulative disadvantage, reinforcing existing economic disparities (Iammarino et al., 2019). These dynamics underscore the importance of embedding AI policy within broader regional

development frameworks.

Taken together, the survey responses point toward a pattern in which artificial intelligence in the participating organizations is perceived primarily as task restructuring and competence intensification rather than as labour substitution. Interpreted through a rural and territorial development lens, these patterns raise the question of whether similar processes unfold unevenly across territorially differentiated and rural and lower-density contexts. Human capital development under AI is contingent upon structured organizational mediation mechanisms, particularly training institutionalization and governance transparency. The observed response patterns are consistent with the theoretical proposition advanced in this study that AI-driven workplace transformation may be understood as a multi-level process in which task reconfiguration, organizational capability, and territorial context interact to shape human capital development. In the present study, however, the territorial dimension remains interpretive rather than empirically tested.

Conclusions

This study examined artificial intelligence as a structurally transformative force within organizational work environments and analyzed its implications for human capital development in a territorially differentiated context. By integrating theoretical perspectives on task-based technological change, augmentation versus automation, socio-technical systems theory, and dynamic capability development with empirical evidence from Latvian organizations, the study advances a multi-level understanding of AI-driven transformation. The conclusions are structured in two parts: first, the empirical contribution of the study, and second, its theoretical implications for understanding AI integration in organizational contexts.

Empirical contribution

1. Within the surveyed sample, responses point toward a pattern in which artificial intelligence is perceived to operate through task reconfiguration rather than direct labour substitution. Within the sample, AI adoption is perceived to be associated with increased work efficiency and intensified competence requirements, suggesting that technological integration may reshape task composition and elevate demand for analytical, interpretative, and adaptive capabilities. In this respect, the observed responses are consistent with augmentation-oriented interpretations of AI, where technology complements rather than replaces human labor.

2. At the organizational level, the survey responses suggest that human capital development is not an automatic consequence of technological adoption. The depth and sustainability of transformation depend on structured learning mechanisms, transparent governance frameworks, and effective internal communication. The survey responses are consistent with the view that organizations institutionalizing training and clarifying AI implementation principles may be better positioned to convert technological integration into long-term capability upgrading. Causal confirmation lies beyond the scope of this exploratory study. Conversely, where organizational mediation mechanisms remain weak, AI may generate skill pressure without corresponding competence consolidation.

3. AI visibility and employee understanding are uneven across workplaces. A small number of respondents reported uncertainty about whether AI is used in their workplace, suggesting that AI functionalities may be embedded in everyday tools and processes without being explicitly labelled or recognized as AI. This indicates that employee sense-making and awareness are important preconditions for sustainable capability development: without a clear understanding of where and how AI shapes work tasks, organizations may realize efficiency gains while leaving competence formation fragmented. Accordingly, transparent internal communication, practical guidance, and clear principles for AI use function not merely as supportive practices but as structural mechanisms that help employees translate AI-enabled task changes into coherent skill development trajectories.

4. The study advances a conceptual proposition that AI-driven transformation is territorially mediated and therefore relevant to rural and regional development research. This proposition is not tested empirically in the present sample, since the survey instrument did not include regional identifiers. The observed heterogeneity in AI integration depth is consistent with, but not diagnostic of, territorial differentiation. Regionally stratified confirmatory research is required to examine whether in rural and lower-density contexts AI adoption remains predominantly operational unless supported by systemic learning infrastructures.

Theoretical implications

5. The study proposes that artificial intelligence may be conceptualized not merely as an isolated technological innovation, but as a capability-dependent organizational process embedded within territorially differentiated development contexts. Sustainable human capital development under AI requires systematic alignment between task restructuring, organizational capability development, and regional innovation ecosystems. Future research should incorporate explicit territorial segmentation and longitudinal designs to further examine how AI reshapes human capital trajectories across diverse structural environments.

6. The present study constitutes the first, exploratory and conceptual stage of a broader research programme. A planned follow-up study will employ a larger, probabilistically sampled, and regionally stratified dataset, including explicit rural-urban identifiers and inferential statistical analysis, to empirically test the territorial and capability-based propositions developed

here and to assess their relevance for rural and regional development policy.

Taken together, the findings point to AI-related workplace transformation in Latvian organizations as an organizationally mediated process rather than a purely technological shift.

Given the exploratory design of the study, future research using longitudinal and territorially segmented data is needed to assess the durability and broader generalizability of these patterns.

AI-BASED IMAGE CLASSIFICATION FOR HEN EGG FERTILITY DETECTION

***Sausthene Landry Tsiguia Tetangmo, Liga Paura**

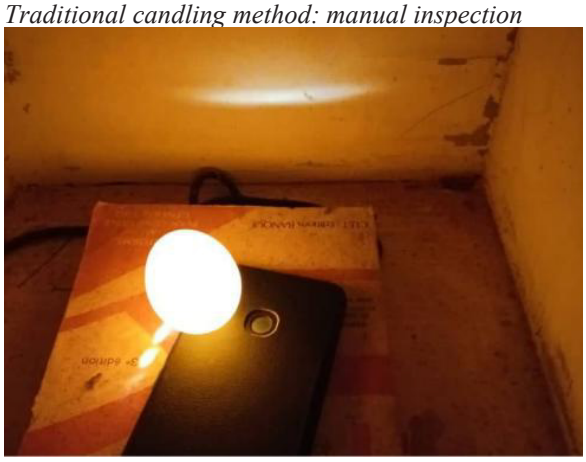
Abstract
Automating early detection of fertilized hen eggs improves hatchery efficiency by reducing labour and misclassification. This study develops and evaluates an AI-based image classification pipeline that distinguishes fertile from non-fertile eggs using candled images. A balanced dataset of 740 labelled images (370 fertile, 370 non-fertile) was collected under a controlled LED candling setup at day seven of incubation, with fixed camera and backlight geometry to reduce acquisition variability. Images were pre-processed (resized, normalised, optional grayscale) and augmented (rotation, flipping, brightness/contrast, zoom, noise). We implemented and compared three models: a convolutional neural network (CNN) trained with cross-entropy loss and Adam optimizer, a Random Forest classifier using handcrafted features, and a Support Vector Machine with RBF kernel. Models were tuned on an 80/10/10 train/validation/test split with stratified class proportions, complemented by k-fold cross-validation for robustness, and evaluated using accuracy, precision, recall, and F1-score alongside confusion matrices. Paired statistical tests indicated significant differences between the CNN and both classical baselines on the main metrics. The proposed CNN combined with image enhancement achieved the best overall performance (test accuracy approximately 85%), demonstrating improved reliability over manual candling and classical baselines. We also provide deployment artefacts including an inference API, Docker packaging, and CI/CD considerations for real-world integration. Generalisation may be limited by dataset size and single-site acquisition; future work will explore temporal imaging across incubation days, transfer learning, and domain adaptation for diverse shell types and hatchery environments.
Keywords: egg fertility, convolutional neural network, image processing, data augmentation, hatchery automation.



Introduction

Automated assessment of hen egg fertility is increasingly relevant to hatchery efficiency and incubator utilisation. Fertility is conventionally determined by candling (Figure 1), in which light transmitted through the shell reveals embryonic development; the method remains labour-intensive, operator-dependent, and sensitive to lighting and shell opacity (Hall et al., 2023a; Ramiro et al., 2018). Misclassification rates for manual candling have been reported at up to approximately 20%, with consequences for wasted capacity and loss of viable embryos. Image-based systems that apply computer vision and machine learning therefore continue to attract interest as scalable alternatives (Kamilaris & Prenafeta-Boldú, 2018; Liakos et al., 2018), and convolutional neural networks (CNNs) in particular have achieved promising separation of fertile and non-fertile candled eggs (LeCun et al., 2015).

A substantial body of work has addressed egg fertility classification from candled and incubator imagery. Studies have employed custom CNN architectures, object-detection frameworks such as YOLO and Mask R-CNN, and transfer learning with ImageNet backbones including VGG16, ResNet50, InceptionNet, and MobileNet (Pooja et al., 2025). Transfer-learning pipelines have reported test accuracies exceeding 98% for several pretrained networks (Saifullah, 2023), whereas detection–segmentation approaches based on Mask R-CNN with ResNet50 enable localisation of embryonic structures (Çevik et al., 2022). Despite this progress, published studies often differ in dataset scale, imaging protocol, incubation day, and—critically—in whether deep models are compared with classical machine-learning baselines on identical, stratified partitions of the same labelled corpus.

Accordingly, the objectives of this study are threefold: first, to construct a balanced dataset of candled images acquired at Day 7 of incubation from eggs collected and incubated under a documented protocol in Cameroon; second, to implement and evaluate a VGG16-based transfer-learning classifier comprising a frozen ImageNet feature extractor and a trainable binary classification head; and third, to benchmark its performance against Random Forest and Support Vector Machine (SVM) models. Additionally, to deliver a reproducible training and inference workflow, including containerised deployment, suitable for hatchery use.

Figure 1
Traditional candling method: manual inspection

Materials and Methods

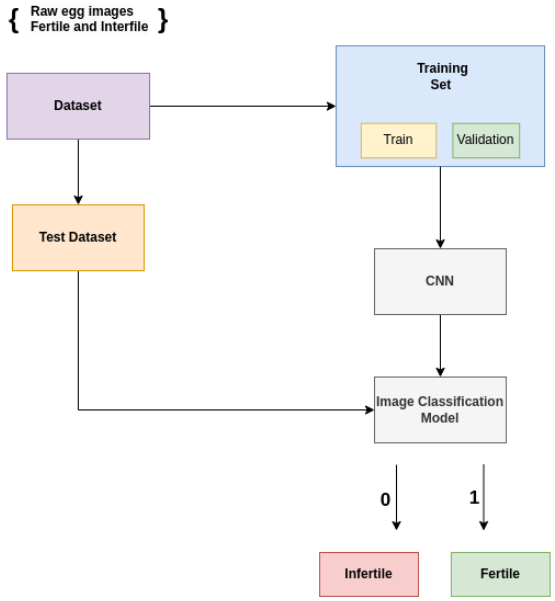
Dataset and acquisition

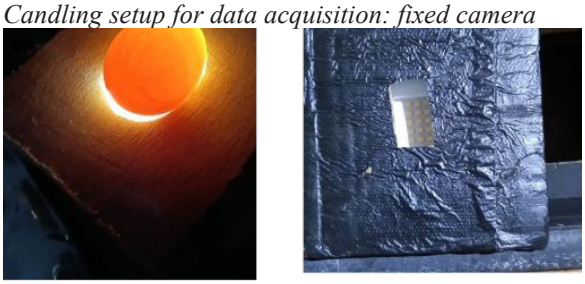
The eggs were collected from farmers in two cities of Cameroon, Yaoundé and Bafoussam, who produce on average 160 eggs per week. The eggs were harvested under controlled temperature and humidity conditions, at least two days after laying. Each egg was checked to ensure that there were no cracks or stains before being

immediately placed in an incubator set at 37.5 °C and 50% humidity. The incubators, with a capacity of 90 eggs each, totaled three units: two in Yaoundé and one in Bafoussam.

A balanced corpus of 740 candled images was subsequently collected: 370 labelled fertile and 370 labelled non-fertile. Images were captured at Day 7 of incubation (standard candling window) with a fixed camera above a wooden platform with a circular cut-out, coated matte black, and a bright LED backlight in a darkened room (Figure 3); camera settings (low ISO, fast shutter, narrow aperture) were held constant. Each image was labelled as fertile or non-fertile by experienced technicians; ambiguous cases were resolved by consensus. Images were collected with permission from the collaborating hatchery; no personal data are included. The dataset was split into 80% training (592 images), 10% validation (74), and 10% test (74), stratified by class (Figure 2).

Figure 2
Dataset flow: train, validation, and test split





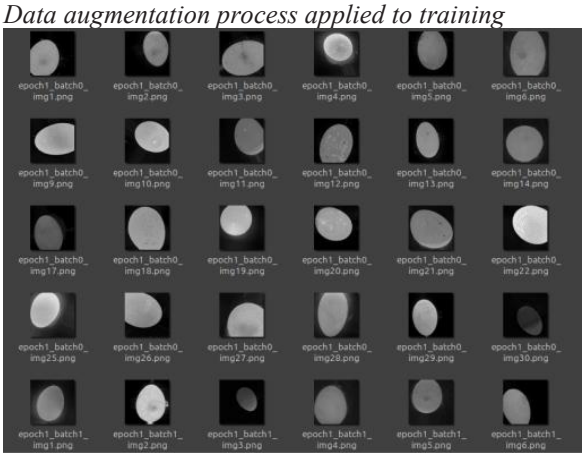


Figure 3
Candling setup for data acquisition: fixed camera

Preprocessing and augmentation

Images were resized to 512×512 pixels and pixel values normalised to [0,1] to meet consistent input requirements for the models (Liakos et al., 2018); optional CLAHE and gamma corrections were evaluated to improve contrast under varying lighting. Data augmentation is widely used to improve generalisation and robustness in image classification, especially when dataset size is limited (Alomar et al., 2023; Mumuni A. & Mumuni F., 2022). Augmentations (Figure 4) included rotations (±30◦), horizontal and vertical flips, brightness/contrast jitter, small zoom/crops, and additive Gaussian noise, applied on-the-fly during training to simulate lighting and orientation variability (Mumuni A. & Mumuni F., 2022).

Figure 4
Data augmentation process applied to training

Models and models training

Three supervised classifiers were implemented and evaluated on the same stratified train/validation/test partitions (80% training, 10% validation, 10% test). The primary model was a deep convolutional network based on the VGG16 architecture (Figure 5), formulated as binary classification of whole candled images rather than object detection. This design follows transfer-learning studies in egg fertility imaging (Saifullah, 2023; Pooja et al., 2025) and provides a direct comparison with classical machine-learning baselines trained on the same labels.

Each candled image was represented as a 512×512 grayscale array with pixel intensities linearly scaled to [0, 1]. Inputs were expanded to three channels and forwarded through a VGG16 backbone pretrained on ImageNet, from which the original classification layers were removed and the convolutional weights were kept fixed during training. Spatial responses were summarised by global average pooling and mapped to a fully connected layer of 128 units with rectified linear unit activation, followed by dropout (probability 0.5) and a sigmoid output denoting the estimated probability of fertility. Parameters were estimated by minimising binary cross-entropy with the Adam optimizer (mini-batch size 32). Training was limited to 20 epochs with on-the-fly augmentation as described above; training was halted early when validation loss ceased to improve, and the learning rate was reduced on plateau. Supplementary k-fold cross-validation was used to assess stability. Unless stated otherwise, metrics in Tables 1–5 refer to this VGG16 classifier.

For comparison, a Random Forest ensemble (Figure 6) and a Support Vector Machine (SVM) with radial basis

function kernel (Figure 7) were trained on flattened grayscale pixel vectors extracted from the same images, with feature standardisation applied before SVM fitting. These models serve as transparent benchmarks when GPU resources are limited or training sets are small (Çevik et al., 2022; Kamilaris & Prenafeta-Boldú, 2018).

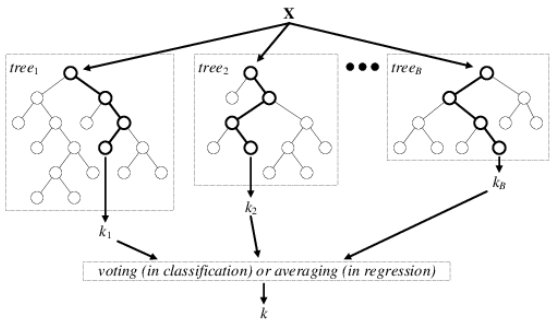

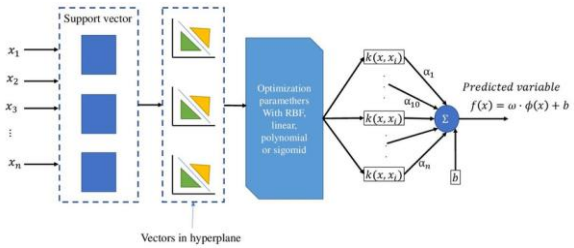

Figure 7
SVM framework with RBF kernel for non-linear classification

Models Evaluation

Model performance was assessed on the held-out test set and, for robustness, via k-fold cross-validation. Primary metrics were accuracy, precision, recall, and F1-score, which are standard for binary classification and allow trade-offs between false positives and false negatives to be quantified (Liakos et al., 2018). Confusion matrices were computed for class-wise analysis, following common practice in agricultural and egg-imaging studies (Ahmed et al., 2025). Pairwise statistical comparison between models used paired t-tests on the per-fold metric values at 95% confidence to test whether differences in accuracy, precision, recall, and F1(4) were significant.

The evaluation metrics are defined as follows (positive class = fertile; TP=true positives, TN=true negatives, FP=false positives, FN=false negatives):

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

$$F1 = \frac{2\times Precision\times Recall}{Precision+Recall} \quad (4)$$

Computational environment

Model training and evaluation for this study were performed on a Linux operating system running Linux Mint 22 (Wilma), kernel version 6.8.0-51-generic, with an x86_64 architecture, on a Dell Inc. Precision 5480 workstation. The processor was an Intel64 Family 6 Model 186 Stepping 2, GenuineIntel (13th Gen Intel(R) Core(TM) i7-13800H, up to 5.2 GHz). The workstation was also equipped with an NVIDIA RTX 2000 Ada Generation Laptop GPU and Intel Iris Xe integrated graphics. Python 3.12.3, compiled with GCC 13.2.0 64-bit (AMD64), was used for all computational tasks within the project virtual environment fertile-env. The environment included a comprehensive range of packages such as TensorFlow 2.18.0, Keras 3.7.0, NumPy 2.0.2, pandas 2.2.3, matplotlib 3.9.2, seaborn 0.13.2, scikit-learn 1.5.2, SciPy 1.14.1, OpenCV 4.10.0.84, Pillow 11.0.0, and h5py 3.12.1, among others. The system featured 14 physical CPU cores (20 logical cores) and 32.0 GB of RAM.

Results and Discussion

Overview of experimental results

Table 1 summarises model performance on the held-out test set: mean accuracy (1), precision (2), recall (3), and F1-score (4) with standard deviation across folds for the CNN, Random Forest, and SVM. The CNN achieves the highest metrics (accuracy 0.85, F1 0.85), followed by Random Forest (0.76, 0.77) and SVM (0.73, 0.75); recall is relatively high for all models, indicating fewer missed fertile eggs. Table 2 reports the pairwise statistical comparison (t-test): the CNN shows statistically significant gains over both Random Forest and SVM (all four metrics, $p < 0.05$), while differences between Random Forest and SVM are smaller and not significant.

Our results align with recent literature in the field; for instance, Çevik et al., 2022 reported strong performance of deep learning for egg fertility detection, consistent with our CNN results. Ensemble

CNNs can achieve high accuracy on small image datasets (Phung & Rhee, 2019), which aligns with our setup (740 images, 80/10/10 split). For Random Forest, sample selection strongly affects image-classification performance (Millard & Richardson, 2015); our RF baseline (76% accuracy) is in line with typical RF image results when limited training data are used. Trebar & Steele (2008) found SVMs effective but sensitive to feature design in classification tasks; our SVM (73% accuracy) reflects the challenge of hand-crafted features compared with the CNN. Chaganti et al. (2020). compared SVM and CNN for image classification and reported higher accuracy with CNNs, matching our ordering (CNN > RF > SVM). Overall, the reported accuracies (CNN ~85%, RF ~76%, SVM ~73%) are comparable to those in similar egg-fertility or small-scale image-classification studies.

Table 1

Performance comparison on the test set

Model	Accuracy	Precision	Recall	F1-Score
CNN	0.8503±0.07	0.8204±0.07	0.8804±0.07	0.8500±0.07
Random Forest	0.7622±0.06	0.7326±0.06	0.8125±0.06	0.7720±0.06
SVM	0.7262±0.07	0.6804±0.08	0.8245±0.07	0.7480±0.07

Notes: Mean ± s.d. across folds.

Table 2

Statistical comparison of performance metrics (t-test)

Comparison	*Accuracy*	*Precision*	*Recall*	*F1-Score*
CNN vs Random Forest	+9% *	+9% *	+7% *	+8% *
CNN vs SVM	+13% *	+14% *	+6% *	+11% *
Random Forest vs SVM	+4% ns	+5% ns	−1% ns	+3% s

Significance: * $p < 0.05$; ns = not significant; s = small effect.

Confusion matrices

Confusion matrices were computed on the held-out test set to inspect class-wise predictions (fertile vs non-fertile). Reporting confusion matrices is standard in egg-fertility and agricultural image-classification studies. Tables 3–5 show the corresponding counts (TP, TN, FP, FN) for the CNN, Random Forest, and SVM on one representative test split ($n = 74$, 37 per class); Table 1 instead reports mean metrics across k folds. The CNN (Table 3) achieves the highest diagonal counts (33 true positives, 30 true negatives) and the fewest false negatives (4), which is desirable when minimising missed fertile eggs. Random Forest (Table 4) and SVM (Table 5) show more false positives (11 and 14 respectively) and slightly more false negatives (7 and 6), consistent with their lower precision and recall in Table 1.

Key findings

The CNN produced the strongest overall performance and generalisation (Table 1), benefiting from end-to-end feature learning and augmentation, consistent with prior work on deep learning for egg fertility classification (Çevik et al., 2022) and with the general advantage of CNNs over hand-crafted features in image tasks (Chaganti et al., 2020; LeCun et al., 2015). Random Forest was faster to train and useful when compute is limited, in line with its role as an efficient baseline in image classification; SVM required careful feature scaling and kernel tuning to reach comparable recall (Trebar & Steele, 2008). The statistically significant gains of the CNN over both baselines (Table 2) support its selection for deployment.

Model performance summary: CNN, Random Forest and SVM maximum metrics

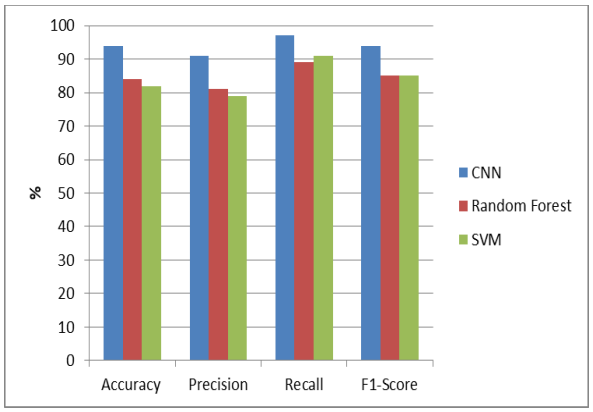

Table 3

Confusion matrix: CNN (test set)

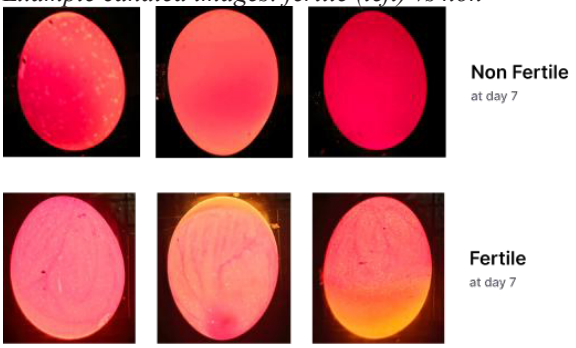
	Predicted	
Actual	Fertile	Non-fertile
Fertile	33 (TP)	4 (FN)
Non-fertile	7 (FP)	30 (TN)

Table 4

Confusion matrix: Random Forest (test set)

	Predicted	
Actual	Fertile	Non-fertile
Fertile	30 (TP)	7 (FN)
Non-fertile	11 (FP)	26 (TN)

Table 5



Confusion matrix: SVM (test set)

	Predicted	
Actual	Fertile	Non-fertile
Fertile	31 (TP)	6 (FN)
Non-fertile	14 (FP)	23 (TN)

Error analysis

Errors were dominated by false negatives where embryo features were faint or occluded by thick shells. The confusion matrices (Tables 3–5) show that all three models tended to miss fertile eggs (false negatives) more often when the embryo was poorly visible or the shell was thick; the CNN reduced this effect (fewest FN). Figure 9 shows representative fertile and non-fertile examples.

Figure 9
Example candled images: fertile (left) vs non

Ablation studies and practical notes

Ablations. To assess the contribution of individual components, we ran the CNN with selected changes. Removing data augmentation increased validation loss variance across epochs and reduced test F1(4) by several points, confirming that augmentation improves generalisation on the limited dataset (Mumuni A. & Mumuni F., 2022). CLAHE and gamma correction were evaluated as optional preprocessing steps; they gave a small improvement on low-contrast images where the embryo was hard to distinguish, but were not essential under our controlled lighting. Training and inference with grayscale inputs (single channel) achieved performance comparable to RGB with lower memory and compute, consistent with the importance of intensity and texture over colour for candling-based fertility cues.

Practical deployment. The classification threshold (sigmoid output) can be tuned to the hatchery cost structure: lowering the threshold favours recall (fewer false negatives, fewer fertile eggs discarded) at the cost of more false positives, whereas raising it favours precision. The best performing CNN was packaged as a REST-style inference API (e.g. Flask) that accepts an image and returns a fertility prediction; the API and model dependencies were containerised with Docker for reproducible deployment across environments. CI/CD pipelines (e.g. Jenkins or GitLab CI) can automate build, test, and deployment so that model or code updates are rolled out consistently to hatchery systems.

Quantifying operational benefits. Automation of candling has the potential to improve classification consistency, labour productivity, and hatchery economics. Although end-to-end operational gains were not measured in the field, the present experiments yield indicators that can be used to evaluate these outcomes.

Classification accuracy. Performance was assessed on the held-out test set using accuracy, precision, recall, F1-score, and confusion matrices (Tables 1 and 3–5). The CNN achieved 85% overall accuracy and 88% recall for fertile eggs (four false negatives among 37 fertile cases; Table 3), with fewer missed fertile eggs than the Random Forest (seven false negatives) and SVM (six false negatives) baselines. Manual candling error rates of up to approximately 20% reported in the literature provide an external benchmark; nevertheless, a definitive comparison with expert technicians requires a paired validation study in which the same images are classified independently by experienced candlers and by the deployed model.

Labour and throughput. Labour demand can be compared using a time-and-motion study that records mean seconds per egg for manual inspection (handling, positioning, and visual decision) versus the workflow adopted here (standardised image acquisition at a fixed station followed by batch inference via the REST API). Scaling time per egg to a per-1,000-egg basis permits direct estimation of staffing requirements; standardised imaging and automated inference additionally reduce variability associated with operator skill and ambient lighting.

Economic impact. Hatchery costs can be related to model outputs by combining false-positive and false-negative rates from the confusion matrices with unit costs for discarding fertile eggs and incubating non-fertile eggs, and by selecting an appropriate classification threshold (see Practical deployment). This study reports the classification error rates required for such an analysis; farm-level wage and revenue data were not collected.

Limitations

The dataset size (740 images) and single-site collection limit generalisability; multi-site, multi-breed data and temporal imaging across incubation days are recommended for future work to capture variability in shells, breeds, and equipment. Claims regarding superior accuracy relative to manual candling and reductions in labour cost were not established through a paired human–machine trial or hatchery economic survey; frameworks for evaluating these outcomes are presented under Quantifying operational benefits. All images were acquired under controlled lighting and camera settings, so performance in more variable hatchery environments (different rigs, cameras, or operators) may be lower unless the model is retrained or adapted with additional data. Thick or opaque shells (Figure 10) can hinder candling visibility (Hall et al., 2023b), which also affects automated detection and remains challenging for both human operators and AI systems (Çevik et al., 2022). The current work focuses on binary fertility classification at Day 7 only; extending to earlier/later incubation stages or multi-class embryo development labels will require larger datasets and careful re-evaluation of model performance and thresholds.

Conclusions

This study fulfilled the three objectives set out in the Introduction:

1. Dataset. A balanced corpus of 740 candled egg images was built with a documented egg-collection and incubation protocol and a fixed LED candling setup at Day 7.

Figure 10
Eggs with different shell types; thickness and opacity affect candling visibility

2. Model comparison. The objective of evaluating machine learning models for egg fertility detection was accomplished: the CNN achieved approximately 85% accuracy on the held-out test set, significantly outperforming Random Forest (76%) and SVM (73%) with statistically significant differences (Table 2), and was therefore selected for deployment as a prototype.
3. Reproducible pipeline and deployment. Training and evaluation code, preprocessing and augmentation settings, saved model weights, a REST-style inference API, and Docker packaging were delivered as deployment-ready artefacts for hatchery workflows.
4. Despite the modest dataset size, the results support the feasibility of AI-based fertility classification under controlled candling conditions. Data augmentation and preprocessing helped mitigate lighting and image-quality variability.
5. The results suggest that AI-based egg fertility detection has significant potential for commercial hatcheries (Çevik et al., 2022): automating candling can improve accuracy, reduce labour costs, and integrate with existing hatchery management systems—claims that are discussed in terms of measurable indicators under Quantifying operational benefits and that require confirmation in paired human–machine and hatchery cost studies.
6. Limitations include the modest dataset size (740 images) and sensitivity to eggshell thickness and lighting. Future work will expand datasets (including multiple species and incubation stages), consider transfer learning and multi-class classification by embryo stage, and integrate with automated sorting and predictive analytics for hatch-rate optimisation.

AI-ENABLED RECOMMENDER SYSTEMS IN TOURISM:A SYSTEMATIC REVIEW OF HYBRID METHODS, SOCIAL MEDIA DATA AND USER SATISFACTION

***Pradeep Sharma, Tatjana Rubina**
Latvia University of Life Sciences and Technologies, Latvia
*Corresponding author's email: pradeepchobe@gmail.com

Abstract
As digital tourism platforms grow in size, they are increasingly adopting artificial intelligence and recommender systems to assist users in dealing with the vast amount of information about destinations, accommodations, events and reviews. Tourism recommendation is a challenging domain because a tourist's choices are influenced by their preference history, social network, seasonality, mobility, location, trust, and perceived usefulness of recommended services. This paper aims to systematically review the latest literature on AI-based recommender systems in the tourism sector, focusing on hybrid approaches, social media data and user satisfaction. The review is conducted in accordance with the literature-review design, which is based on transparent search, eligibility and thematic-synthesis principles. In total, the search process identified 92 records; after duplicate removal and screening, 31 full texts were assessed, and 19 publications were retained for thematic synthesis. Searches were conducted on peer-reviewed research related to tourism, travel, hospitality, smart tourism and point-of-interest recommendation. The review reveals that hybrid approaches are extensively discussed, as they can integrate collaborative filtering, content-based filtering, knowledge-based reasoning, contextual variables and AI-based representation learning. The literature reviewed, however, also reveals some common pitfalls, such as limited data, platform bias, privacy issues, and lack of real-world validation and satisfaction. The paper concludes by suggesting that future research on tourism recommender systems should link algorithmic accuracy to user-centred outcomes, transparent evaluation, responsible use of social data and value for destination management.
Keywords: AI-enabled recommender systems, tourism, hybrid recommendation, social media data, user satisfaction.

Introduction

Tourism is an information-rich industry, where tourists evaluate a multitude of different places, modes of transport, hotels and accommodation, restaurants, events and activities before booking or visiting. Hence, recommender systems are applicable in that they help to filter out the vast number of alternatives, based on the user's preferences and the characteristics of the items (Chaudhari & Thakkar, 2019). In digital tourism, AI-powered recommendations become particularly significant as platforms need to decipher behavioural patterns, location cues, review text, and context to offer personalised suggestions and recommendations (Bulchand-Gidumal, 2022).

A typical tourism recommender system will attempt to predict a tourist a value, for example, a location, service or tourism experience, at a specific time. This prediction can be made using collaborative filtering, which is based on the behaviour of similar users, or content-based filtering, which compares items with known user preferences with the attributes of attractions, hotels, activities or destinations (Roy & Dutta, 2022). They are effective but can only be used individually, as tourist behaviour can be influenced by time, season, travel purpose, group composition, location and immediate travel constraints (Rehman Khan et al., 2021).

Hybrid approaches are one of the most prominent research trends in recommender-systems research, as they are able to leverage the merits of various approaches. A hybrid tourism system can be a combination of collaborative filtering and content-based information, contextual variables, knowledge-based constraints, graph models or social-media signals (Fararni et al., 2021). This combination is useful because the decision to visit a destination is rarely based on a single factor. For example, a tourist may prefer museums, but weather, opening hours, distance, cost, and social reviews can cause them to change their mind (Massimo & Ricci, 2022).

The data from social media has also influenced the design of tourism recommendations. Information on perceived service quality and destination experience is conveyed through reviews, ratings, images, tags, check-ins and geotagged posts (Chang et al., 2019). User-generated content can provide a better and faster indication of the current trends and visitors' sentiments than formal tourism databases, and thus can be utilised for recommendation in dynamic destination environments (Missaoui et al., 2019). But this evidence is not neutral, as social media platforms may have noisy, biased, duplicated or strategically manipulated content (Li et al., 2021).

User satisfaction is a key result of tourism recommender systems, as a technically correct recommendation does not necessarily imply a satisfying travel suggestion. A recommendation can be high in an offline dataset, but if it is not convenient, poorly explained, unsafe, culturally inappropriate, or not in line with the purpose of the trip, it will not work (Ricci et al., 2022). Therefore, satisfaction is a user-centred construct in the present paper that is related to usefulness, trust, transparency, timeliness, diversity and decision support (Fan et al., 2022).

This paper aims to systematically review the literature in the field of AI-based recommender systems in the tourism industry with particular emphasis on hybrid approaches, social media data and user satisfaction. The review is based on three questions. Firstly, which hybrid and AI-based approaches are mentioned in

tourism recommender-system research? Secondly, how is social media or user-generated content utilised in tourism recommendation? Third, what are the concepts of user satisfaction, trust and evaluation found in the studies reviewed?

Materials and Methods

This paper was intended to be a systematic literature review. A systematic review is suitable because the aim is to locate, structure and analyse the current research and not to create a new prototype software or to simulate performance results. The PRISMA style of reporting requires the authors to describe the process of record identification, screening and inclusion, which enhances transparency and reproducibility (Page et al., 2021).

Peer-reviewed academic literature was reviewed for the topics of AI-powered recommender systems in tourism, travel, hospitality, smart tourism and point-of-interest recommendation. In order to plan the database searching, it was decided to use Scopus, Web of Science, IEEE Xplore, ACM Digital Library, ScienceDirect, SpringerLink and Google Scholar as they include both computing and tourism research. The search strings included the combination of the terms 'tourism recommender system', 'travel recommendation', 'AI recommendation', 'hybrid recommender', 'context-aware recommendation', 'social media data', 'user-generated content', 'tourist satisfaction' and 'point-of-interest recommendation'.

The inclusion criteria were that the publications had to be written in English, peer-reviewed, and directly related to tourism or travel recommendations. Studies also had to include at least one of the following dimensions: hybrid recommendation, data from social media, user-generated content, contextual adaptation, AI-based modelling, trust, satisfaction or user evaluation. Following Aggarwal's (2016) general recommender-system framework, broader recommender-system studies were only included if they offered concepts that are crucial to understanding tourism applications, such as hybridisation or evaluation practice.

Editorials, theses, non-academic reports, non-English publications (unless reliable translation was available), and papers that referred to tourism only indirectly were excluded. Studies were also excluded if they made unsupported claims with no method, data, review protocol or evaluation logic. This was a significant choice, as there are instances in recommender-system literature that combine conceptual frameworks, prototype descriptions and empirical claims without making the evidence and the proposal distinct.

The screening process comprised title and abstract screening, and full-text eligibility assessment. The title and abstract stage determined if the study was related to tourism recommendation or if it included the topics of AI, hybrid methods, social data or satisfaction. The full-text stage assessed the methodological detail provided in the paper to support extraction and synthesis. Before thematic analysis, duplicate records and inaccessible full texts were eliminated.

The screening log was introduced to enhance transparency of the screening process. A total of 92 records were initially found in the database and Google Scholar. Of the 74 titles and abstracts screened, 18 were duplicates and removed. Forty-three records were removed at the title and abstract stage due to not being focused on tourism recommendation, not using AI/hybrid/social-media methods, or not being relevant to user evaluation. Thirty-one full texts were then evaluated, and 19 publications were included in the final thematic synthesis based on the inclusion and exclusion criteria.

The quality assessment was used in a practical manner as it involved studies from both the computing and tourism outlets. Studies that explicitly stated the source of their data, the task of the recommendation, the algorithmic method used, the evaluation method and the limitations of the study were considered stronger. When a study made general statements of accuracy or satisfaction, but did not provide details of how this was measured, the study was treated with caution. This is in line with the general rule that systematic reviews should be transparent about the evidence-selection process, and not assume that all publications are equally reliable (Page et al., 2021).

Data extraction was done in both technical and tourism categories. Technical categories were algorithm type, hybridisation strategy, use of context, use of social media data, evaluation metric and type of dataset. Recommended item, destination setting, user need, satisfaction measure, trust-related feature and practical implication were the categories related to tourism. This is because the evaluation of a tourism recommender system should not only be considered as an algorithm but also as a service-support tool.

The information in the datasets was also coded as the reviewed studies used different forms of evidence. Public or platform-visible sources comprised ratings, reviews and TripAdvisor/social-media content, as shown in the social media analytics and mobile tourism recommendation studies (Chang et al., 2019; Missaoui et al., 2019). Other studies used destination metadata, point-of-interest categories, location traces, routes, or user-item interactions or platform-specific logs that are frequently private or not easily replicable (Massimo & Ricci, 2022; Hamid et al., 2021). In contrast, review-based studies aggregated existing datasets, algorithms and evaluation metrics instead of creating new user logs (Chaudhari & Thakkar, 2019; Roy & Dutta, 2022).

The synthesis was thematic and not statistical. A meta-analysis was not possible due to the significant differences in the datasets, destinations, algorithms, evaluation metrics and research design of the studies reviewed. Thematic synthesis enabled the evidence to be clustered into the following emergent areas: hybrid methods, social media and user-generated content, context awareness, user satisfaction, trust, evaluation

practice and responsible AI. This way, it also did not create false comparisons of numbers across studies that were not directly comparable.

Literature review

Recommender systems can be defined as information-filtering systems that are able to predict users' preferences based on their past interactions with the system, the description of the items or some contextual information (Aggarwal, 2016). In the context of tourism, this broad definition gets complicated as the recommended item could be a destination, an itinerary, a hotel, a restaurant, an event, an attraction or a point of interest (Chaudhari & Thakkar, 2019). Tourism products are also experiential and perishable; thus, the similarity of the products is not the only factor that influences a good recommendation, but also the traveller's situation and expectations (Kontogianni & Alepis, 2020).

Table 1

Inclusion and exclusion criteria for selecting studies (Author-developed criteria based on systematic-review reporting principles)

Criterion	Inclusion criteria	Exclusion criteria
Study type	Peer-reviewed journal articles and conference papers	Editorials, theses, white papers, blogs and non-academic reports
Language	Publications written in English	Non-English publications without reliable translation
Publication period	Main focus on 2019-2026, with foundational sources retained when needed	Outdated papers with no conceptual or methodological relevance
Domain	Tourism, travel, hospitality, smart tourism, destination or point-of-interest recommendation	General recommender-system papers with no tourism application or implication
Core topic	AI-enabled recommendation, hybrid methods, context awareness, social media data, user satisfaction or trust	Papers unrelated to recommendation methods, tourism data or user evaluation
Quality requirement	Clear method, dataset, review logic or evaluation approach	Unsupported claims, unclear method or inaccessible full text

One of the most popular recommendation methods is collaborative filtering, which can be used to find similarities among users or items and make predictions based on these similarities. It can be helpful when there is enough user-rating or interaction data, but can suffer from cold-start issues when there is little data for new users, new destinations or new services (Roy & Dutta, 2022). This can be mitigated by content-based filtering, which considers item attributes such as location, category, facilities, price range, or textual description (Massimo & Ricci, 2022).

Context-aware recommendation is especially relevant in the tourism sector as tourists make their decisions in a varying context. Context can be time of day, season, weather, distance, transport available, crowding, travel companion, budget and purpose of travel (Rehman Khan et al., 2021). The context-aware tourism system can then adjust the recommendations if the user changes location, the weather conditions change, or if a planned activity is no longer suitable (Hamid et al., 2021).

With the advent of AI and machine learning, tourism recommendation has gone beyond traditional similarity matching. Complex relationships between users, locations, reviews, images and sequences of behaviours can be processed using deep learning and representation learning (Deldjoo et al., 2020). Because tourism decisions are often made in the context of networks of places and experiences, graph-based recommendation can capture the relationship between tourists, destinations, activities and social connections. Social media and user-generated content are now a key source of tourism analytics. Ratings, comments, photos, geotags and check-ins on review platforms and social networking websites can offer information about real visitors' experiences (Chang et al., 2019). These data sources can enhance the recommendation as they contain opinions and contextual indications which are not necessarily present in formal destination descriptions (Missaoui et al., 2019). Meanwhile, online reviews can be biased towards extreme experiences or popular destinations, and towards active users, leading to fairness and representativeness concerns (Li et al., 2021).

Thus, Responsible AI is part of the conceptual background for tourism recommendation. For this review, responsible AI is defined as privacy protection, consent, bias reduction, explainability, fairness, and avoiding harmful destination-management effects. These concerns are important as recommender systems can rely on personal profiles, location traces and signals from social media, and popularity-biased recommendations can over-expose already popular destinations and restrict visibility for smaller or less digitally visible ones (Fan et al., 2022; Li et al., 2021; Rehman Khan et al., 2021).

Evaluation is also a methodological challenge, as shown in the literature. Many recommender-system research studies use offline metrics like precision, recall, RMSE and ranking accuracy (Silveira et al., 2019). While these measures are helpful to compare algorithms, they do not fully reflect whether travellers trust, understand or enjoy the recommendation (Ricci et al., 2022). Thus, the user-centred evaluation should

be included in tourism recommendation, particularly when it aims to enhance user satisfaction and decision quality (Fan et al., 2022).

A significant stream of literature is related to multimedia/multimodal recommendation. The communication of tourism experiences is often done through pictures, videos, maps, and short textual reviews, and so the content of the media can better depict the atmosphere of a tourist destination than just the rating alone (Deldjoo et al., 2020). This is significant for AI-powered tourism recommendations as visual and textual cues could be used to differentiate locations with the same formal classification that offer different experiences for visitors (Li et al., 2021).

In the field of smart tourism, research is also focused on the relationship between recommendations and the broader digital destination infrastructure. Smart tourism systems are a set of systems that include sensors, mobile apps, platform data and internet-based services to assist in pre- and in-trip decision-making (Kontogianni & Alepis, 2020). Recommendation systems in this context are not standalone algorithms, but part of a service ecosystem, such as maps, booking engines, review sites, and destination-management organisations (Hamid et al., 2021).

The literature on sustainable e-tourism also indicates that the consequences of recommendations should be assessed in terms of social and destination-level consequences. Contextual Suggestion systems can guide the travellers towards more appropriate and less congested alternatives by considering location, time, and user needs as inputs to the decision-making process (Rehman Khan et al., 2021). This is significant as recommender systems can either alleviate the pressure on popular attractions or exacerbate it if they only encourage popularity and click behaviour.

Results and Discussion

Hybrid approaches for tourism recommender systems

The literature reviewed shows that hybrid recommendation is one of the most important directions in tourism. The hybrid systems are appealing since the decision-making process of tourists involves preference history, destination attributes, situational constraints and social influence (Fararni et al., 2021). One approach is usually not enough, as collaborative filtering can fail to recommend new attractions and content-based filtering can fail to capture trends from similar travellers (Roy & Dutta, 2022).

There are several ways in which hybridisation can take place. There are also hybrid collaborative/content-based systems that aim to balance user similarity with the description of the content (Çano & Morisio, 2019). Other systems add contextual information like location, season or weather to adjust the recommendations during the trip (Rehman Khan et al., 2021). When recommendations need to take into account constraints like budget, accessibility, opening time or family suitability, knowledge-based rules can also be added (Ricci et al., 2022).

Hybrid AI systems are gaining attention because they seamlessly combine structured and unstructured tourism data. Structured data consists of ratings, prices, attraction categories, locations, opening hours, booking records and user-item interaction matrices. Written reviews, social-media posts, images and videos and free-text destination descriptions are all examples of unstructured data. Sentiment or topic features can be extracted from textual reviews, and images and multimedia descriptions can produce more comprehensive representations of destinations (Deldjoo et al., 2020; Chang et al., 2019). Graph-based approaches can also be used to model relations between users, places, categories and social links, which can be useful when tourist behaviour forms networks of movements and experiences (Gao et al., 2022).

Although these are the advantages of hybrid methods, they also come with design challenges. While many data sources can be combined to enhance representation, this can also make the system harder to explain and reproduce (Fan et al., 2022). Tourism studies should, therefore, document the components that are mixed, the reasons for choosing the hybrid approach, and the assessment of each component's contribution. In the absence of this transparency, hybrid recommendations can be a general term and not a well-tested approach to methodology.

Social media data and user-generated content

The data from social media has a unique value for tourism recommendations as it reflects visitors' perceptions and popularity of the destination in near-real environments. Reviews and ratings are explicit feedback on attractions, hotels, restaurants and activities (Chang et al., 2019). Visitors' location can be displayed through check-ins, geotags and posts, as well as the time they visit and their description of the visit (Missaoui et al., 2019).

User-generated content can add value to destination profiles, beyond official descriptions. A formal database might classify a site as a museum, and reviews might indicate that the visitors connect it to family learning, long lines, high admission fees or cultural value (Li et al., 2021). This distinction is important because travellers will often choose based on perceived experience and not just on category alone. Sentiment analysis and topic modelling can thus be used to find out what users actually talk about when it comes to the qualities of a recommender system (Chang et al., 2019).

Recommendation is also trend-sensitive, based on social data. The demand for tourism can shift rapidly due to festivals, weather, online exposure, seasonal events or viral content. A recommender system based on recent social signals is likely to react faster than a system based on historical ratings (Missaoui et al., 2019). But trend sensitivity should be applied wisely since popularity does not necessarily equate to suitability for all travellers. Excessive reliance on

social popularity can lead to a lack of destination diversity, placing additional pressure on already over-visited locations.

Ethical and methodological issues are also present. The information in social media can contain personal data, location data, and culturally sensitive data, posing privacy concerns (Fan et al., 2022). Online reviews can be fake, promotional, incomplete or biased to those who had a good or bad experience (Li et al., 2021). Therefore, research with social media data should include a description of data cleaning, bias control, privacy protection, and limitations of the platforms.

Awareness of context, personalisation, real-time adaptation

One of the characteristics that distinguishes tourism recommendation from many other domains is context awareness. A film or music recommendation might hold relevance for weeks, whereas a tourism recommendation might not be relevant within hours, due to changing weather, distance, crowding or opening time (Rehman Khan et al., 2021). Thus, location-aware and time-aware systems play a crucial role as travellers may require suggestions while they are already on the move in a destination (Hamid et al., 2021).

Another essential personalisation factor to consider in tourism is the purpose of the trip. A business traveller, family tourist, backpacker and cultural tourist will appreciate different aspects of a destination. User preferences should thus be captured in more specific ways, e.g. relaxing in nature, walking, visiting authentic countryside places, visiting family businesses, enjoying local cuisine, exploring culture and traditions. The average rating system may indicate popular places but not take into account whether it matches the traveller's needs and preferences (Massimo & Ricci, 2022). These situational rules can be added to preference prediction by contextual and knowledge-based elements (Ricci et al., 2022).

Real-time adaptation is useful but should not be overemphasised. According to the literature on smart tourism, the use of current data is recommended to increase the relevance; however, a review paper should not make any claims to real-time performance if the system has not been deployed and tested under real conditions (Kontogianni & Alepis, 2020). A more defensible statement is that the literature suggests that real-time adaptation is a viable design path, but further and more rigorous testing is required.

Explainability is also an issue with the context and personalisation. When a system suggests an indoor attraction due to rain, or because the user has expressed a preference for cultural attractions, the suggestion is more readily accepted if the reason for the suggestion is apparent. Explanations can contribute to user satisfaction as they help to decrease uncertainty and indicate that the system is reacting to the travel situation (Fan et al., 2022).

User satisfaction, trust and practice of evaluation

One of the outcomes is user satisfaction, which is not always reported in the literature. For instance, Silveira et al. (2019) demonstrate that the evaluation of recommender systems is frequently based on offline accuracy measures like precision, recall, RMSE and ranking performance. In addition to these technical aspects, Ricci et al. (2022) suggest that user-centred evaluation should be performed, and Fan et al. (2022) link trust, transparency, privacy and fairness to the perceived quality of recommendations. Thus, offline accuracy can be useful for technical comparison, but is not an exhaustive measure of tourist acceptance, trust or enjoyment of the recommendation.

Trust plays a particularly critical role in tourism as it is related to the cost, time, safety and emotional expectations of the decision. Reviews and ratings can boost trust by demonstrating that other visitors have had a good experience with the service or destination recommended (Chang et al., 2019). Explanation features are also able to help build trust by providing the reasons why an item was recommended and what data were used (Fan et al., 2022).

Based on the literature reviewed, satisfaction is a multi-dimensional phenomenon. In the literature on the evaluation of recommender systems and trustworthy-recommendation research, relevance, novelty, diversity, convenience, transparency, privacy, response time and trust are repeatedly associated with the quality of recommendations and user acceptance. Even a technically correct recommendation can be unsuccessful if it draws tourists to overcrowded destinations or to services that are inappropriate to their needs. Future research should therefore be based on algorithmic measurements as well as user studies and real tourism effects.

Also, destination-management effects should be taken into account in the evaluation. Recommendation systems can be problematic if they keep recommending the same popular destinations, thereby increasing their visibility while decreasing visibility of smaller local businesses. The sustainable tourism recommendation should thus take into account diversity, fairness and spatial distribution and not only the short-term click or booking likelihood (Rehman Khan et al., 2021). This is especially relevant in the context of rural and regional tourism, where recommendation systems can shape the distribution of visitors and the potential economic prospects.

Challenges and gaps for research

Real-world validation is an area of literature that is lacking. Many tourism recommender-system papers have been introduced that present architectures or frameworks, and few papers have tested systems with real tourists in real destination environments (Hamid et al., 2021; Rehman Khan et al., 2021; Silveira et al., 2019). This minimises the opportunity to connect algorithmic results to real satisfaction, trust and re-use. Field studies need to be reinforced, because the

behaviour of tourists is also affected by the limitations of the devices, the internet connection, the stress of travelling, the cultural expectations and the changing environmental conditions.

Other missing elements are transparency of the datasets used in tourism recommender-system studies. The literature reviewed is public and/or platform-visible review/social-media data, including TripAdvisor reviews, and location traces and destination-specific POI datasets that are not always reproducible (Chang et al., 2019; Missaoui et al., 2019; Massimo & Ricci, 2022). Public datasets can be used for comparison but may not reflect current platform behaviour or multilingual content or local destination diversity. Future research should give adequate detail of data sources, data pre-processing, access status, privacy protection and limitations.

Moreover, responsible AI is still poorly developed in many of the studies on tourism recommender systems (RS) which are based on profiles, location traces and social-media data. Recommendation systems can mimic popularity bias, exclude less popular destinations, or make recommendations based on sensitive behavioural signals. The use of location traces, social media posts or user profiles is a specific concern with regard to privacy (Fan et al., 2022). Thus, data governance, consent, bias mitigation and explainability should be considered as design issues in tourism research, and not as minor limitations.
